SURGERY OF THE EXTREMITIES

DISEASES OF THE BONES, JOINTS MUSCLES TENDONS CONDITIONS COMMONLY FOUND IN THE EXTREMITIES

Ashhurst, A. P. G. Multiple Cartilaginous Exostoses. 4 nn S. g. Ph la. 9 o lvii 67

Ehrenfried has recently studied the clinical entity which goes under the name of multiple cartilaginous exotoses and prefers the name hereditary deforming chrondrodysplasia. He was able to find only about a dozia cause which had been reported in America the greatest number of cases being reported from (erman) and France to the author has seen 11 c ses within the last ten years be on cludes that the disease a not so rare a 1 seem but that it has been overlooked or knowed.

The underlying nathology is not the exostoses, but a chrondrodysplasia affecting especially the metaphyses of the long bones, though the bones of the pelvia, the clavides scapule, and the vert bree may be involved. The eniphysis is small or musshapen the intermediary cartilage is narrow irreg ular, oblique or rigzag and sometimes prematurely ossified. Scattered alo g the ends I the shaft beneath the periosteum are dumps or nests of cartilage cells persisting uncakified where they are left in the process of growth. Later these groups may develop into the cartilaginous exostoses, which give the disease its name but these are merely incidental. A malignant osteocartilaginous tumor may develop in one of these exostoses. Certain secondary char cteristics usually are p esent such as low stat re due to the shortness of the limbs, particularly the l wer There often is a lack of growth of the ulan and nes valgus is frequent as the result of the lack of growth of the fibula. The disease is transmitted by both affected males and females and by unaffected females but there is no evidence that it may be transmitted through unaffected males

The a thor report cases which be has between and two others from the service of T vi which be did not have the opport nity to observe In addition be reports y cases which p escut so askeletal deformities and evidence of being hereditary but which are examples of some type of cho drodysplata

Davidson, A J Subungual Excetosis. 1m J Orth Sure o 0 50.

The author observed 5 cases of painful e large ment of the distal extremity of the great to ed e to subungual exostosis. They were all makes under 50 years of age. No history of mury infection could be obtained. The process requires from aix to twenty four months to develop sufficiently to cause the pellent to seek advice.

The etfology of exostones in general may be summed up as (1) those d to direct infection (2) those due to direct trauma (3) those associated with tendon or ligamentous strain 1. e static.

In the cases referred to by the author there was no history of infection of any kind now were there any inflammatory signs of either the matrix of the nail, the bose of the soft parts. Exostoses of the variety described could not be credited to any sesociated tendinous or ligamentous strain for the reason that no tendion or ligament is attacked to the portion of bose from which the growth a rises.

By excluding these possible explanations it brings us to a consideration of trauma. The location of the exotoxis is at a point which is frequently the site of trivial injuries and which is being constantly subjected to the continued pressure of the stiff box lig of shoes. The usual strophic conditions of the factor muscles of the toes have the effect of increasing the power of the extensors, placing the toes in a position to bear the broat of this shoe pressure Regardless of the fact that no history of direct traums could be obtained in any of his reported cases, Davidson thinks it is quite possible that subungual xostoses a e the result of trivial highress occus following the prolonged irritation of shoe pressure which may or may not be appreciated by the patient.

Berry J. M. R. tarded Ossification as an Etiologic Factor in Traumatic Arthritis and Epiphysiti J. Am. M. Au. 9 6 1 1 468

Three cases are reported in boys seven to ten years pain a lawling in the symptoms are the same pain a lawling in the jol to of the lower extremity a light rise in temperat and some limit it on motil Vary examination is when retardation in os thention in the real involved and also in the wrist.

The cases show that retarded osufication may be a envolved fact in the production of traumatic arthritis and epiphyshis in children. The trauman in such cases consusts in vestration of the joint due to thormal activity. The child may be leading the normal activity. The child may be leading the normal activity. The child may be leading the normal activity of the child of his own gre but anatomically in belongs that you see early searn voonager and to a old strain his citivities bould be correspondingly respicted. Cases of this character are probably out componed and the ery antito be

Flux, G. Treatment of Purulent Arthritis of the knee by Arthristomy or Marcuptallimiton of th Synonial Soc (Le traitement des rthrift purulentes du genou par l'arthrotomie ou saraplaiisation de l'ynoviale) Prr = d d o 6 p. 7

overlooked or wrongly diagnosed.

Flexx affirms that in injuries of the knee joint one of the f ctors which engenders rapidity of supported diffication is the difficulty of drainage or rather inefficacy of evacuation with drainage. Vecording to Delore and Kocher arthrotom for drainage is a blind method which is often insufficient.

Fleax ha observed in the wounded cases under his care that there was retention of puts in the serous on ity in spite of the presence of several large permeable drains. From close bestvation he cam to the conclusion that it was the drain itself that formed the obstacle to drainage. He therefore replaced arthrotomy with drainage by arthrotomy creating one or more articular mouths kept wide open which llowed the continuous evacuation of the infected joint contents without the aid of any tube. He gives the details of seven cases treated in this manner.

This method of exacuation of the knee-joint in no way obridate the indications for rescriben of the knee which have recently been formulated by Tuffier and others but it is incontest the that the mire quickly and better seyfic product are evacuated from the synovial spaces, the less the indications are for resection. This is why bo thinks that throsport of the content of the con

tomy is superior to arthrotomy increases with drain age tubes W. A. B. rread

Dunlop J. A Deposit in the Supraspinatus Muscle Simulating Subacromial Bursitis in I Ork Surg ut 1 0

The author reports a case of a large leposit about the tendon of the suprispinitua a well as a considerable deposit in the belly of the muscle demonstrated by tereoroentgenorum

The treatmert in tituted was a plast 1 11 aricast such as a used in the abdu 11 n positi n for
fracture of the neck of the hum rus. This was applied under nitrous oxide angesthesia. Wer ten
days the most was removed and the support and
position were gralually done away with. Hot air
bakes are useful in such cases in relieving pain and
hastening the return of normal motion.

McGhnnan A Fracture of the Neck of th Fern r a Study of the Treatment and I'nd Results of 85 Cases N g G Ph)

The 1th report as of training the personal observation in the pit eight years. In this series, 30 recent for tures and old fracture were treated and 12 nations were treated and 12 nations were treated.

In all cases full abduction with d waward true ton and inn tri totati in was the positi in obtained in the reduction of the true. The full abduction was assured by fivation of the pelvis by abducting the sound leg and the innaud rotation by litting the trochanter forward. Impaction was separated in 6 cases and in the eventh was not disturbed because the impaction occurred with abduction of the thigh. This is an unique observation.

Various forms of treation were used from tirm plast r of Paris cast to loose tying out of the thighs Direct extension by ice tongs was used in 3 handi capped patients one of whom died Salling the fracture was done twice.

For the old cases bone graft was used once nall ing twice removal of head once sultrochanted osteotom; twice freshening fragments once Of the recent cases four died and in one the fracture failed to unite. One of the old cases, caulted fatally and the patient still walks on crutches 7

years after treatment. Treatment was refused by young adults, with vicious union. Ten patients were not treated on account of feetheres and circulatory julimonary resalt or nervous symptoms. Two are living several years after the injury aged 88 and so years, and the proposing results of the proposition of the propos

capacity is noted in to cases, the average loss being 5 per cent, after a period of disability lasting from 6 months to 1 year and 5 months with an erage close to 1 year. The occupation if these patients inclided botel manager rest rateur if mer housekeeper seamstress laborer tallor motormen and market driver.

SURGERY OF THE BONES, IOLNIS, ETC.

Burckhardt H., and Landols, F. Experiences in the Treatment of Infected Joints in War (Erfahrungen ueber die B handlung 6 unten Geleuk m Kriege) Beil 11 Chr. o ceili 358

The authors have reported their methods in a previous communicat! but we then nable to report on the end results. They now report these

end results and are ble to state their conclusions on more definite basis. This study is a contribution to the question whether resection of a joint is justifiable in war or not

I all severe cases of joint infection, the Indications alone must decide whether resection or amputation is to be resorted to Resect in its generally done () in the field hospital as part of the immediate treatment of the wound () later on on some vital inductal when amputation is voided (3) after looser period when it is thought to effect bealing

f a bronic joint suppuration

The most important and the most frequently observed cases of joi t infection are those of the kine-joint, which when badly infected are almost importa t a hip-joint i fections as regards

Imports t a hip-joint i fections as regards relation t lif and function. If the fissures extend well into the tibia amputation is the best method, but if amputation i not do then radical resect in with ablation of the bone end is preferable to simpler procedures.

Regarding individual joints resect! in the case of the hand foot and llow joints gives good result. In the case of the knee-joint resection is indicated if the general six is good and there into a modern the endough of the best with the modern of the patient in the patient in

place can be assured. But the general results re poor and although the limb is preserved pseudar threas: usually results. Nevertheless, resection or at least some simpler operation should be tried

when the above conditions are present. If they are not then amputation must be done to save the patient's life.

In the shoulder joint resection gives better results. In infected hip-joints, the casualties are very great and resection very rarely saves the lite of the patient.

N. A. Ber 20.4.

Hollman P An Overlapping Joint as a Substitute for Cunciform Osteotomy 1 m J Orth S 1

The author devised an operation that ubstitutes for the simple train erap joint made in the cune form section an overlapping one that is less liable to displa ement. There is an underlying simple general plan that involves two linear cuts and the removal of (w) riers of bone no matter what the degree of angularity.

The first cut is perpendi ular to the long axis of one of the arm of the deformed bone on a le el with the apex is the angle on the concave if of the bend. This divides the bone into a longer and a shorter

segment

The second 'ut is made perpendicular to the long am of the longer segment on a plane parallel with but distal to the cut that would have been made in a cuneiform osteotomy. The more distal this plane the longer will be the overlapping tongue is the r sulturn joint.

Next the end of the longer eigment is turned out through the kin incision and a orner is removed from its deeper side. The longitudinal cut should be parallel to the long axis of the segment and should divide the bone equally the transver-secut should be on a level with what was the aper of the

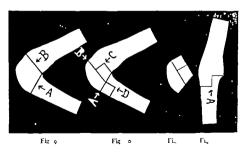

angle nother neare of other former. The least agree in groupe half the thickness of the born on the uper half of the the end of the large segment. Next a smarts out to mother uper half at name projection from the other than the at name projecting from the indicate of the two smeets half in each half the two smeets half in each half the two smeets half in each half the componing duerram that the projection for the smean range of the smean range

can be inserted consequently a very bique fracture is held as accurately in position as if it are transverse. The tissues are disturbed but alginity the technique is simple, the procedure rapid. The hellow cylinder permits new medullary and bone formation, and being of the tinness it its a paper (two-thousandits of an inch in thickness) the steel can corried away.

Chaptot Resection of Almost the Whole of the Humertus for Fistulous Ostromyrdiths, Followed by Ossetus Reprod ction Without Shortenints and with the Production of a New Humarial Head (Resection de 1a presque totalist to the Chapter of the Chapter in the Chapter of the Chapter of the Chapter of the Chapter production d'une têts humertus nouvelle; Ball of meto Sec. 4 dir 4 Per 9 6, till, 43.

The author reports a case of multifathous entenmyelith in a boy of 16. In February 9.4 Chaput resected from 21.15 cm. of the lower part of the humerus. Later on in M y 1914, owing to the development of a faitble the upper third of the humerus comprising the articular extremity was ablated. Cleatination occurred in from two 1 three months the bonn reproduced and united with the new bone of the lower region.

This reproduction of almost the entire humerus Chaput explains as being due to the preservation of the personsteum and the youth of the patie to Up to the twentieth year the regenerative power of personsteum is very active. After thirty grafts re-indispensable

The continued use of atension in this case prevented shortening. The reproduction of the humeral head is very interest ig. It has only been possible owing to the abundant formation of he which has been facilitated by movement. W. A. B. rox.

Albee F N A Statistical Study of 539 Cases of Potts Disease Treated by Bone-Graft Am J Orik S 1 9 6 d 34

With the object of securing report of results obtained by others with the bone graft treatment of Potts allease a large number of printed questions were sent t surgeous in this and foreign countries

who had performed this operation. Thirty-three surposs reported a total of any results in any of which the disease was pron unced arrested in 50 th co dition was improved. Of the any patient 12 deed, 4 f these fastalities being reported as due t shock. The remaining 8 cases died four months or longer after the operation, either from complications or from intercurrent diseases. In 5 of these cases the symptoms from april 1 diseases were entirely controlled. In 3 of the 1 cases in which death was due to shock, the chief and mallet were used to obtain the grafts.

Of the 33 surgeons 16 reported on per cent of the cases as disease rrested o reported that they did not use plaster jackets or spinal support beyond the period of immediate post-operative recum bency o reported so pe cent of cases arrested and one secured 88 per cent if good results.

Of the author's personal cases ally those that have bee operated upon on year or longer are included in this report. There are 50 of these in 184 the dheave was mrated, in there was improvement. To dat 2 died 50 these were entirely relieved of the Pott dhease ymptoms a d died of some intercurre t disease.

One case died of an unknown cause the day after operat on one died of cetomark on the fourth day one from matta lymphat! I not one died of cetomark on the fourth day one from matta lymphat! I not not support to the died two years after operatin from suppurate meninglish following a skull injury. Autorysy showed complete cure of the tubercul us spine. One deel of portumenta one week after operation. Others died of amyloid degeneration of the viscers utherruclosis of the lu g, and an next abdominal condition. Only 3 of the sign assets his deel of tuberculous meningitis In no case has the been my trouble with the tilva from which the grit we removed.

The ges of the patt is varied from 20 months to 65 year. (N the t tal 530 axes the disease was arreated in 460 th of the was proved in 50 in 20 impro ed. The were 9 deaths after operation. In 6 instance, death occurred long after operation and after all pinal symptoms were entire.

ORTHOPEDICS IN GENERAL

Corner E. M Deformities of the Feet. Cl. a 6 xl as

The author discusses various deformities of the feet from the standpoint of the normal positions and movements of the foot. Deformities are variations from these normal conditions. The foot t rest normally is in a position of moderate calcaneus while the active foot is in a position of talipes equinus. At the ankle joint the movements of dorsal and plantar flexion of the foot occur at the midtarnal oint abduction and add ction occur. Pes planus is a deformity of abduction and per cavus is o adduction. Abduction causes a depression of the normal arch of the foot but paredoxical as it may seem some persons have all the symptoms of flatness of the foot bet nevertheless have an arched instep-By means of diagrams h shows the occurrence of callogities on the soles of the feet which are caused by the assumption of these varied positions, thus the abducted foot has its typical localized collosities, the adducted its own, etc. The deformities of the active foot, talipes equinus and pes cavus, usually cause few symptoms, but the deformities of the in active foot tallpes calcaneus and pes planus, require treatment.

At the met tamophalangeal joints, he describes the deformity of hallu rigidus which in the active position develops into hallux extensus and in the inactive position, into hallux flexus. These are caused by bosses of bone developing on the dorsal or under surfaces of the head of the matataraal bone. If they grow out laterally they produce hallux valgus or halfux varus depending upon the side they grow upon. The treatment is the operative removal of these bony outgrowths, with the wearing of properly shaped boots. R S BEITWEE

Lorett, R. W : Th Superstition of Flat Foot. Pulletrics o 6 exvill. 6.

From a st dy of the feet if 800 nurses the author concludes that the troubles ordinarily described as flat-foot, "procated-foot, and weak foot are not due t any particular type o structure of foot. A foot with a high rch was found to be slightly less enduring than the low-erch type. He concluded that the trouble was due t muscular strain. Frequently the arch of the sole of the boot is not so high as the arch of the foot and this is ant to cause strain.

Painful rigid flat-foot should be treated by manipulation under ether or by operation. Painful flexible flat-foot or foot strain will require the temprary use of a support. The arch of the sole of the shoe should lso be raised sufficiently t support the arch of the foot I Burney

Schmidt M. Congenital and Especially Bilateral Elevation of the Scapula (Ueber den angehorenen Schult rhlatthoch nabesondere doppel-citure stand) Zinchr f orthop Chi rres Mar

There are 6 cases in the literat re of bilateral elevation of the scapula. Various theories have been offered as to the cause of the def rmity lack of amnios fluid, existing muscular defect intra terine pollomyelitis, and malformation f the

scapula, also the arrest f the normal descensus of the shoulder-blade

The technique f the oper two which was per formed by \ lpius 18 as follow I clajon long the spine of the scapula directly t the bone elevation of the periosteum and entire resection if the bony part of the fossa supraspinata. O'Rellly A. Results of Non-operativ Treatment of Infantile Paralysis. 1 m J Orth Surg 9 'n

The author's paper is based on tudy of the cases of infantile paralysis treated at the out-patient clinic of the St Louis Children a Hosp tal and the Washing ton University Medical School Th maj rity of cases seen were paralyses of the lower extremity The muscles are put n eq ilibrium and all strain is removed from the weak or paralyzed muscles. I the majority of cases brace is applied. Originally the brace was attached to the shoe I two years sandals have been used. Any deformity due to co tractures which does not yield to tretching is corrected by tenotomies.

The patients come to the clinic three days a week for massage and muscle training a d the mothers are instructed how to massage them on the ther days.

From an analysis of 1 4 cases treated the nthor concludes that it is very difficult t treat infantile paralysis non-operatively in an out patient clini owing to the difficulty of inducing the patient to attend regularly for any length of time

From 40 to 45 per cent of the cases show some improvement when treated by braces and this perce t age is not materially increased by the use of massage Improvement in all cases in which t was used was not great and recovery of muscle power in stretched and exhausted muscles seems to be slight. In the majority f cases no improvement took place after six months especially in the more severe cases. He believes that o e is saf in ope ting n any case of infantile paralysis after the first year and that it should be done in uit ble cases. PRI LANIX

Cates, B B Spina Bifida B (# M -> 5 J

The author reports 9 cases of spina binda coming under his care making in all 16 cases which he has treated. The ages arried from 21 days to 72 years though with the exception of 2 the ages averaged about eight weeks. The history of each is given in full. Of the author's 16 cases to survived beyond a post-operative period of three months lie believes that the age of the patient is not su han important factor in determining the personal equation as the physical condition and believes the surgeon may with a clear conscience urge the lesser of two evils operation under the most favor able conditions rath r than rupture with risk of infection and memoratis.

Fail C. R. Righting.

Rugh J T Bone-Grafting for Spinal Conditions Report of Forty Cases 4m J Only 5 g

The author claims six advantages for the bonc grafting operation viz

- r It accomplishes fixation in less than a year in marked contrast to the four to ten years required by other methods.
- 2 Under this fixation treatment nature will more rapidly fill in or soli lify the diseased area
- 3 An abscess formed or in the process of forms tion will usually disappear without tapping or opening

4 Very I w mortality

- 5 Manipulations are all ione in normal healthy
- 6 The economic advantage which in the case of the wage earner makes him an independent member it the community within a year

In his experience with forty cases Rugh has found no disadvantages that can be attributed to the

operation per se

He believes that the operative fixation of the spine is the treatment of hoice for spinal caries and certain other conditions and especially so in cases past 12 or 14 years of age. He reports a series of forty operations with 74.3 per cent of excellent results and Lange's requirements were fulfilled in that he placed the brace under the skin and shottened the time of efficient recovery.

PHILIP LEWIS

Claude, II and L Hermitte J Anatomo-clinical Study of a Case of Tomi Section of the Spinal Cord (Etude anatomo-cliniqu d n cast de section 1 t le de la moelle) B ll 1 mem Soc med d help d Par 9 6 xxvii 476

The authors consider that the case now reported upon by them presents a louble interest inasmuch as it show unusual clinical expressions of total section fothers in lord and that it permits for

localizing the origin of certain reflexes which up to n w have been matters of discussion

There is no certain symptom which allows the lagnous of total section of the spiral or d whi some patients exhibit all the classical sympt in yet anatomical examination frove that the most respective of the section o

The patient was a soldier who in consequence of injuries presented a vertebral fracture with viry marked gibbosity in the region of the eighth final forsal apophysis. Examination 19 days ft rithe miurs showed complete anasthesia as far as th eleventh dorsal root complet abolition of the refu han and achillean reflexes and of the loveralid minal reflex a inversion of the plantar rutan our reflex absolute retention of urinc relaxation of the anal sphin ter etc. Forty-eight days att r the injury there was a reappearance of the tend n reflexes which were exaggerated Eight days later defense movements of the lower limbs were noted and within a few weeks more there were automatic movements of the limbs. These movements were preserved up to the time of the patient's death which ic urred four and one half months after the injur-

The reappearance of the automatic movement suggested a very severe compression rather than a total section of the cord and surgical interference was suggested but refused by the pati in

Autopsy clearly showed that there was a fracture of the dorsal vertebra the spinal cord was not only compressed but literally crushed this crushing corresponding to a total action. There was complete isolation of the lumbar and dorsal cord as well as of the encephalic connections.

The authors observe that their fin hings show that while in the majority of cases of total section their is a fixed paraplegia with muscular bypotonus and sholition of tendon reflexes yet sometimes after such symptoms there may be clinically a restoration of certain rendon reflexes even an exaggeration of them and an increase of reflexes of leftines and of spontaneous movement. The phenomena displayed by the author's patient was in contradition to the law of Jackson Bastian according to which every complete section of the cord i a companied by an absolute anaethesia and a flaccit paraples with d unite abolition of the tendinous reflexes.

The authors account for the evaggerated ten! a reflexes by the compression of the lower trush of the cord owing to the presence of an anterio dura mater nodule. This slight compression by increasing the dynamism of the gray matter seem to be the most add cause of the ten hinou purarific trity. As regards the defense movement the uthors agree with Wari. I oliv and Depenne the 1th are due to medullar, aut matum.

In further considering the phenomena observed in their case, the authors observe that the preserva if n f the spinal vessels assured the lower segment a better nutrition than in case where the isolated segment is despited of all vascular connection with the curcipalli, segment. Moreover in their case the circulation of the explaints at their case the circulation of the explaints at their case the circulation of the explaints at their case their case to be circulated to the explaints and their case of the explaints are their case of their case

Jonas, A. F. Dialocation of the First Corrical Vertebra Produced by Manipulation T. 4ss. Surg Aus Washington, 9 6 M y

Th author reports one case which is made the subject of his paper. The pattent was a farmer who appeared fo enumination in August 915 with his bend dropped forward, face partly turned toward the right skde, and his chin resting on his stem on this overbrown were highly devated. His neck secured to be fixed for he did not mak the slightest cervical rotation. A Internal wir disclosed the piper and on the cerviciant of the control of the project of the cervical rotation. A litteral wire disclosured to the project of the cervical rotation of the cervical rotation of the cervical rotation of the cervical project of the cervical

H stated that he had n t been able t turn nor raise his bend for more than a year and that his condition was due to manipulations received t the hands of an esteopath while under treatment fo ge eralized rheumatism. He had been placed his back on an operating table and the treatment was begun with "igorous and forcible rotations of the head. The operator standing at the head of the inble had grasped the patient's head with both hands one resti g on either side of it, two fingers, the Index and middle beneath each honeo tal maxillary ramus, and while bel g h ld thus, his head was twitted from side t side by ttreme nd f refbl rot tions, causing great pain suddenly felt ind heard a loud painful snap in the back of his neck it the base I the skull and his head becam fixed I the position described and had so remained. H. stated that his condition had become unbearable on account of the pun in the back of the neck and occiput and his inability to separate his faws enough t enable him to eat speak with freedom. He had had an almost co

tant vertical headach as well as pain in the neck

since the accident

On examination any attempt to rotate his head caused a marked muscular pasts involving all the caryleal muscles especially the trapedl and attended marked. An onescent projection was not only pulpals but distinctly visible in the occipliocervical space. This appeared to be a spinous proces belonging either to the first or second cervical vertex. The tip of the spine appeared to deviate to the left of the median line. It was tender on pressure and caused the patient to filinch decidedly. In-

spection and palpati of the pharynx disclosed an irregularity and t aderness at the nasopharyn real function.

It was evident that it was a case of luxated cervical vert bra, probably the trut one the tlas. There had been a cord pressure ymptom except for an occasional ti gling of sh rt durati n in both arms and hands. There had been no m tor disturbances all r flexes were normal and careful scarch for sensory changes was egative A skingram ore senting lateral view of the cervical spine revealed a retrodisplacement of the atlas The spac between the posterior margin I the foramen magnum and the first cervical spine was clearly increased. The condition was not clear on first inspectio owing to the fact that the spine if the second cervical vertebra is much larger and longer under ormal conditi na than that of the first the latter usually being absent or rudimentary Further a dislocation t this point without a fracture of transverse or articular process f the axis and abac of cord lead n is improbabl. Theref re, it was vid at that there was a alippoing forward f the head on the tlas involving the occupito-atlantal articulation. The occipital condyle, probably the left one, had slipped forward so that it rested in fro t of the margin f the left uperior articula urf ce of the tlas causing a fixed rotary anterolateral fierd n f the head. The putient was informed of his condition and advised t ret m t th ostcoouth as this class f practit ners consul themsel 🚓 bone-setters. He declared is as prorous Eng would perm t and insisted his ⊷et j that the author make manual luctso. He was informed that this was out of the q two because one could not hone to ed dislocation in this regio that had existed m ruthin a ven in th less hope to an cidental readjustm at and t the same time old an infury to the medull. It was agreed that an effort tim al red tin should be mad ad f upon conful immediat open operation should be done

A cordingly and ութեւ զե ann thesia guarded rotery manipulations with pressure the pr minent cervical spin were carried o 1 and as was expected without results. The nations was placed in the ventral position and brought f recard on the operating table so that his shoulders rested on its edge and the forehead was placed. a Cushing bench. A laminectomy had been planned because it was considered impossible to effect and operative replacement of the dislocated this after having been displaced for m re than year. The chief object to be achieved was to remove the lift avial facet as well as the lamina to enable the putient to elevate his head so as to relieve the pressure f the chin n the chest. Through the usual posterior incision the arch of the atlas together with the left superior articular surface was removed with a rongeur forceps. A distinct anteroposterior movement of the head could not yet be made. The right atlooccipital articulation was affected only in a rotary

way and as its articular surfaces were in one tand immovable it was decil but move n uight the articulate n to mobilize it. The take n plished so that anteroposters r movement 1 am fairly good. The wound was deel and 1 sed in the usual assets mann r. The perative reverse was normal. The in might began to the

Edinger has een the results obtained by Ludloff and Hasslaner with a patients treated in this manner in which cause the distance between the disunited nerve-ends varied from 5 t 5 cm. In every case there was clear evidence of good progress of regeneration in the nerve. Within a few needs the anesthesia area bocame much reduced. He mentions particularly a case in which o cm. of the tibial and 8 cm. of the populetal nerve had been resected. After inserting the agar jelly tube the return of the plantar reflexes was demonstrable after 16 days.

WAR DEMONA.

MISCELLANEOUS

CLINICAL ENTITIES - TUMORS, ULCERS, ABSCESSES, ETC.

Byford, H T The Etiology and Prophylaxia of Cancer Illineis M J 9 6 xxxix, 8

The uthor presents a few fairly well established facts that have led him to draw certain conclusions with regard to the etiology and from these conclusions to formulat such recommendations of prophylactic nature as they may seem to justify

We are justified in assuming for argument s sake, that carcinoma is an infection and that t will not be a waste of time to make a review of facts and

probabilities n this basis.

Although carcinoma is sometimes moculated into the aidn or other external epithelial surface, it is in a great preponderance of cases introduced into the system with the food.

The human faces are carriers of germs of car enoms, both in individuals affected with the duease and in many who are not. Th same may be said as to the faces of the dog and the cat.

The occurrence i primary infection in the colon and upper rectum shows that the germs that get by the panceratic secretions can survive to infect the rectum. If they reach the extum al ve they can if course, be passed out and may find lodgment elsewhere.

Those who are most subject to carcinoma are those wh sow in dirt and ent the greatest variety of food. Thus chimney-sweeps, industrial laborers in large towns city laborers, fourners, and carpenters all of whom have high rat of mortality work in dirt and have not always the means not intensity for frequent analysis, while presument, compositors, and printers, whose working materials are protected from outside contamination and whose surroundings are such that they can and do wash and clean up when they got I unch and go home from work, have a lower rate.

There are probably several factors that have some influence upon th increase of cancer in recent years. The increase of railroad traffic may be supposed to have some effect in agreeding infection through travel of individuals and through the enormous amount of cold storage food that is carried every where. Some if the travelers and some of the food must be infected.

Since duodenal ulcer is a more common lesion than gastric ulcer and yet seldom becomes infected with cardnoma, and since tryptin, which is poured into the duodenum also pre ents continued super field development of carcinoma on surfaces with which it a kept in contact th questi narises whether trypsin, possibly some vegetable for ment avoidable in the contact of the contact

The f llowing ecommendations are suggested Carcinoma should be considired an infectious

disease.

Precautions against the spread of the infection should be taken by the community as well as by the individuals affected.

3 Foods part cularly fruits and vegetables, should be protected from contamination t their source and in transit

4. The disposal of human crement in suburban and populous rural and ma uncertainty districts should be such as t used possibl contamination of surface soil. The frees of patients with car cnown if the alumentary canal and pelvic organs should cerve the same tention as those of patients from typhood fever or cholers. Women abould be taught the infectious nature if normal stoods, with purficular reference to keeping the perineum free from contamination.

5 The numbe of cats and dogs in populous districts should be restricted and they hould not be allowed to roam about the streets by day or night. The excess should be killed. Means should be taken for the enternination f rats, mice, cock roaches, and other vernin.

6. Individuals whose occupati ns are known to expose them to great risk of infection from carcinoma should be taught that it may get into their systems either through the irritated skin or by way of the silmentary canal.

7 All epithelfal areas affected with chronic irritation and erosion should be attended to. An attempt might also be made to prevent infection of ubcrated and eroded surfaces in the allmentary canal. Patients with such belong should avoid all unsterillized food that might be contaminated.

8 Munkipal authorities should put carcinoma upon the list of diseases to be reported in order that the patients may be traced and taught how to take

5.1

care of themselves and thur infected discharges and that none of those living with them be illowed to handle foodstuff for the market

o The blood of patients with car moma should be exhaustively studied with referen c to the dicovery of something that will increase immunity

to The time would seem to be ripe for teaching the public something concerning the erroneous notions about diet that are privalent among the idle rich and prosperous poor in order that they may stop manufacturing the serie us forms of gastrontestinal disease that have of late veins shown such an alarming increase in frequency the seeds of which are shown in adolescence and the fruits of which are shown in adolescence and the fruits of which are shown in adolescence and in sinescence.

11 Women who have not borne childr n for several years should be warned of the danger of d veloping carcinoma and shoull not only be on the lookout for symptoms, but should submit to a pelvic examination at least twice a year until it is evident that the mucous membranes are healthy and are remaining so EDW p EL C R 111.

Moullin C. M: The Classification of Tumors in N C Phil 9 6 1 m 5

The great variety of tumors makes their da, in a uon difficult ind it or rding to the nuthor no previous dissilication can be said to meet. If the requir ments Instead of da adving tumors in the basis of malignancy fracture rongin th author ul muts what his believes to be better classification.

Using the word in its ordinary are extation tumors are divided into two classes. On is due to the reprodu tive power that all tissues naturally possess when sudd alv aroused into action the ther to changes that hould take place in divel pment not being cit; a ntly carried out. The power of reprodu ing th ir like directly without assistance from any oth r source is the ommon property of all living things and all parts. The extent to which they make use of this power furnishes the most satisfactory basis for the classification of tissues and of th tumors that grow from them very carly period of development one group of cells is marked off for reproduction, the germ cells. The rest of the cells known as the somatic cells become specialized for other kinds of work and grad ually lose their reproductive power. Each cell as it develops passes through all the stores through which its ancestors passed in the course of evolution The stru ture of a tumor depends upon the parent stem and always resembles it though it i never so perfect Malignancy of the tumor depends then upon the maturity of the parent cell at the moment the bud began to grow. If the parent cell has al ready reached the adult age the bud will increase proportionately slow pushing the surrounding structures to one side instead of invading them is no separate class of malignant tumors, rapidly growing malignant forms occurring in all classes

Under the head of tumors of the germ organ and

its I no tives the author has included factus in ternal territomata. Varian dermoil and curring additionata. The lassification of the ion that grow from the somatic cells dipends upon that a lopted for the tissues themselves. Every organism I or tissue has its own kind of tumor. Tumors of the three dipending may recomble those of the prostat. Lut behave very differently.

Tumors due to errors in de el i mont differ from those caused by the fullen awakening of the r producti e pever f the tusurs in the tith volo not posses an independ nt siten e and do not belong to the same generation as the tru tures from which they grow or to the next Ir mature arrist f d velopment i one if the most important cruses of tumor formation. This not only involves the r gressi c advince of tissues, but the disappearan e fith we which have ceased to lof use. This group in lud s u h tumors as the mering myel a le c used by failure of the medullary groove to close it its re par time and also those turn is le 1 ping trem their mains of the hyplingual duct or the n littin du te or wherever tissues hi till to had to ar in the evolution of the organi n

Allon A.P. Phantom Tumora (I I) (Al

The type all plantom tumor is room nt as a room to off must be with onforming to that mustle or group of mustle with which it is societed it is loays resonant but less so than the neighboring painter will be and to disappear faring less that it loss not in analohy do so I am is also in though some cases run into a cramp in which ase the pain in the new cases.

The author reports two axes both in women In on the tumor windue to a ontraction of the right rectus muscle. This patient reco ered under suggestion. The second was due 10 a histed carum following mucous collies. It disay per red.

The treatment is to r move any factor of irritation that may be present or if du to occupation con iler the ondition for a remedy Calvanian and massage have proved useful and jurely neurotic cases respond excellently to ugg-ston It is well to bear in mind protective phantom timors and to seek for the cause in deeper or other organs.

Roberts J B A Further Note on the Etiology of Surgical Scarlatina T im S g i Wab ungt n 916 M y

The author states his belief that true scarlatura sometimes occurs by the introduction of the infecting agent through a breach in the sk n insteal of by the usual faucial or nasal route and in his opinion there is reason to believe it at the did colly in solating the infecting grantsm is probably lare to its ultramicroscopic size and its filteral1 nature. He also suggests that the anginose affection, termed scarlatina may cory more than one specific infec

This last opinion is based upon the confusion which has long existed between similar infections such as typins and typhoid fever malarini and yellow fever and othe well-known infections with similar symptoms. Reference is made to the papers of McCarty and Hamilton. He believes that many cases of so-called post-operative scarlet fever are probably of septic origin or are due to vasom tor influences. Instances doubtless occur where the true scarlatinal affection is simply coincidence in a patient already suffering from wound received about the time f exposure to the

infection The cases are cated of Strickler who about so years ago inoculated children with saliva of scarlet lever patients in the hope of producing immunity Strickler believed that he ctually caused acute scarlet fever by introducing the infection through a wound in the skin. The latest investigation of the etiology of this disease known to the uthor is that of Mallory and Medlar of Boston who found a gram-positive bacillus which they thought to be the true causative agent.

SERA, VACCINES, AND PERMENTS

Gellhaus: Som Observations Resording Collar gol Injections in Small Doses (Finire Beolachtungen bei Kollargolinjektionen in kieurin Dosen) Humchen med. Wahntebr 9 6 luffi, 9

The author draws attention to the efficacy of small intra enous injections of collargol in infective diseases. In his earlier cases he used a s and 3 per cent solution, but in his recent practice h has reduced the strength to 1 per cent and in the case of children to o s per cent

He has treated altogether 143 cases f different inflammatory types with collargol. These include appendicitis peritonitis, gonorrhera poeumonia, etc. As a general rule good result are obtained when collargol is injected in the early at ges of the inflammatory process. The action of collargol is found to be powerless only when the infection is of a high degree of virulence

Of the cases treated 34 were cases of appendicitis. Of these operation was necessary in 6 Of the others, died and sy recovered with a cases of relapse The early use of collargol not only facilitates the results of operation when such is ecessary for inflammatory conditions, but it may obviate opera W A. BRENSAN tion altogether

Morriss, W. H. Secondary Harmorrhag in Mili tary Burgery Ilil S pres 96 vix III 3

G MAD E BRILLIAY

ical infurv

The inefficiency of accepted methods of controlling wound infections has been one of the surgical surprises of the present war Almost every case is infected many of them seriously Serious compiles tions frequently arise and one of the most serious is secondary hemorrhage.

Secondary harmorrhage may originate from one of several causes (1) A thrombus closing the end of a severed vessel may become infected digested and harmorrhage result (2) A vessel wall may be contused and harmorrhage occur only after sloughing has occurred (3) An ints 't vessel wall may be eroled by direct extension of a sloughing infection from neighboring tissues (4) A spurious aneurism may have its sast wall infected and rupture occur.

Other factors besides infection whi h may lead to secondary harmorrhage are (1) a harmorrhage diathesis may exist (2) the jolting and jarring incident to transportation may excit harmorrhage und (3) a foreign body in the wound may cause

hæmorrhage by eroding the vessel wall

The onset of secondary homorrhage is usually sudden and the patient may be found in collapse

lying in a pool of blood,

The treatment should attempt the control of the hemorrhage and the resulctation of the patient. The ontrol of the hamorrhage may be secured by ligation of the bleeding vessel as far above the area of infection as possible. Frequently however recurrent hemorrhages occur and a unity amputation if the bleeding vessel be in a limb as high as necessary, is undertaken. The resulctation if the patient is effected highly normal saline hypodymnothes and blood transitution.

The author reports five cases coming under his own observation and gives a complete history of each case.

J. H. Salle

Hess A F The Blood and the Blood Vessels in Hæmophilia and Other Hæmorrhagic Diseases inch i Med 90 vn 03

Hes believes that the group termed the harm orrhagine diseases in fudes a large number of abnormal conditions and that at the present time it is a fruit? So task to attempt to unmyel the various entities embraced by the chinical conditions which are assembled under this general head. This he onsiders as due partly to the fact that the physiology of the roagulation of the blood is still incompletely understood partly because of the impossibility of analyzing the various factors concerned in coagulation and in part because these hemorrhaginates have been incompletely observed from a chinical point of view.

In this investigation therefore the author considers the condition of purpurs rather as an entity and compares it to be morphilla. The main points in his study may be summarized as follows

The coagulation time of the plasma in homophilia at times may become normal without the occurrence of homorrhage or other apparent change in the

condition of the patient

The estimation of the number of blood platelets is of great value as has been found by others, in differentiating between purpurn and hæmophilis. In some cases of purpurs the platelets are abnormal and may be differentiated like other macrocytes

and microcytes of the I lood into macroplatelets and microplatelets

The puncture test—the r a tion following abutaneous puncture of the skin—is an aid to diagno-1. In hom philia a hamorrhagi area rarely result from this procedure in nurpura it is the rule

The capillary resistant test in also of value. By this is unlikestood the reaction following the application for a definite period of a tourniquet to the upper arm. In purputa, this results in petechial hiemorrhages on the forearm in hiemophilia the if in negative.

There is an h relitary purpura as well as an her-ditary hemophilia. This type of purpura should be more generally recognized so that these cases ill not on an outil of their hereditary history, on

tinu to be regarded as hemot hilla

The matern more of a farmly may be a bleed rof the hæmoj hiluae type and the I mate if the pur puritype. The farmlies are less ribed in which one member suffered from hæmoj hilua and another from rurruri.

Hamophilia may be atyrical. A case is reported which showed a altium detriency as born out by various heart all and limital tests (hamophilia

cal (priva)

It is one cases manifest in harmorrhage the cessel seem to be involved. This weakness it en ountier to in hithern and may be origenital it may tribear in the ourse of an infection. Beass, or of a nutritional disorder such as infantile sourcy.

In the classical case the differentiation between hemophila and purpura is simple. The priturof a typical hiemor biling is a mal with a heredit ry history of Heeding whose blood manifests a detinite delay in coagulation time v hose platelets are normal in number bleeding time not increased who shows no hamorrhagic reacts n tollowing subcutaneous puncture of the skin and a negative capillary resistance test. A typi al case of purpura is found to be quite different—the patient may be a male or a female the plasma pagulates in almost normal time and the number of blood platelets is decreased (frequently below 100,000 in number) there is definite subcutaneous hamorrhage follow ing puncture of the skin an increase of the bleeding time and the development of a large number of petechial harmorrhages following the application of GEORGE I BUILDY a tourniquet

Meyer W: The Conservative Treatment of Gan grene of the Extremities Due to Thromboanglitis Obliterans. 1 S r Phila. 9 6 lth 180

Meer a discussion of a number of cases which the author has treated conservatively nith most encounging results and a review of the various methods of treatment of both acute and chronic gangerien of the attenties, the author discusses in detail that type due to thrombo-anguits oblit erans. He believes that conservati e treatment shoull always b instituted before an amputati n

is considered. If gangrene has begun, it is obviously impossible to replace what is dead. The progress may however be at yed old obstinate ulcers may heal, and otherwise uncontrollable pain can

be relieved

Conservative treatment consists in the use of superheated air or Bier hyperæmia. This is best combined with systematic hypodermoclysis of Ringer a solution. If these simpler methods prove of no avail conservative operative measures re indicated viz. tying of the femoral vem or arteriovenous annatomosis. Both of the latter methods should be subjected to further careful clinical research as to their real value. Superheated air treatment may bring improvement of the symptoms, but a lasting beneficial effect is rarely seen. It seldom controls the pain. The systemat hypodermic injection of 400 to 500 ccm. of Ringer s solution (Materina Kora) daily or every second r third day deserves a definit place in the con-servative treatment. Its effect may be lasting or temporary but if temporary repetition usually again brings improvement. Two such series of injections represent a sufficient test as to their usefulness. Internally a simultaneous administration of organotherapeutic preparations deserves a careful test. Since women seem to be immune to the disease it has been suggested that something in their system protects them and for this, if for o other reason, extracts of organs should be given a trial.

Inflammation of the wall of the blood vessels of the next higher group t the capillaries, arterial as well as venous, seems to be responsible for the thrombosis (Buerger) Its cause may be microbic but the fact that women are immun again seems to argue against this. The increased viscosity of the blood via blood that is thicker than normal, seems to play an important rule in the tiology of the disease. It is possible that an altered quality of the blood as such represents a cause for the occurrence of the thrombosis and the subsequent gangrene. On the basis of this reasoning procedures which tend to reduce the congulability of the blood within the body deserve to be tried in an effort to find the underlying cause of the trouble Intravenous injections of anticoegulating substances, such as a s per cent watery sol tion of sodium citrate may prove to be useful adjuvant to the systemic hypodermic administration of Ringer's solution. GATEWOOD.

McLean, A. Venous Thrombosis and Embolism, Its Cause Significance and Consequences. Penne M.J. p. 6 xix, 3 &

The author describes some experiment on dogs undertaken to explain the cause of the thrombotic process which occurs, for instance as a femoral thrombods following an pparently clean append ectomy where the common etiological factors, such as () trauma to the intima, (2) at gnation or

slowing of the blood stream, (3) chemical changes in the blood, and (4) infection re wanting

II was impressed with the tremendous amount of injury a vein could withstand without the formation f a thrombus at the site of the injury

The following phenomena were noticed in the

course of the experim ats

7 When a cin is ligated in continuity the blood in the 'ein will clot only on one side of the point of ligation, that is, the aid from which the blood is coming

In ligating a vein between two ligatures (two inches part) the blood between the lightures clots very slowly and if left for a week or more the con tenis of the ligated vein will have completely disappeared, a fibrous cordlik structure slone remaining

3 The same result is accomplished by ligating

an artery between two ligatures.

4 Simple crushing of rem will not cause a clot at the point of crushing. The crushing can be repeated in forty-eight hours and clot will not form at the site examination of the repeatedly crushed vein tw weeks after the last crushing, will show a thick ening of all the coats of the vein the intima remaining smooth and glistening

5 Crushing the vein with the subsequent introduction of 24 hour bouillon culture of staphylococci, and again crushing the vein, grinding the staphylococci into the vein wall did not produce clot or thrombus at the site of the crushing or the

injection of the bacteria.

6 The introduction of a sterile thread into the lumen of a vein, allowing one-half to three-fourths of n inch to be suspended inside the vein, failed to produce a clot or thrombus.

7 The same xperiment wa negative in the artery allowing the thread to remain four five and seven dava

8 Thread infected with staphylococcus albus or aureus will cause thrombus in three or fou days. Thread infected with colon bacillus or staphy lococcus aureus troduced into an artery caused the formation of a firm clot

to Steril thread one half and one inch long let go i the circulation caused no symptoms.

Infected thread (colon bacillus) let go caused death in thee nd one-half days. Thread infected with blood-clot recovered in the right lung

In reviewing his records of the past two years in 1,010 laparotomies, thromboris and embolism followed in 33 cases 2 per cent. There were 9 fatal cases of embolism. There were 3 cases of pulmonary embolism followed by abscess and recovery: a of hepatic embolism followed by abscess with one recovery 2 of cerebral embolism followed by death. There were fifteen eases of femoral thrombosis follow ing pelvic operations.

It is worthy of note that in all the cases of embollsm and thrombosis in the entire series, there was only one case of embolism with recovery and no cases t all of thromboals that followed operations LUCIUM IL LANDRY in the uppe abdomen.

Painter C. F The Operative Treatment of Thrombo Anglitis Obliterans. St P xl M J

The author cites a number of cases that have come under his observation which he puts in the classification so well described by Leo Buerger

All of his cases were in young Russian Jews. Occupation can not be traced as a causative factor as his cases are found in many different callings. However his observations coincide with Erbs in somuch as excessive eigerette smoking and inveterate tea drinking has been noticed in all his cases. The unstable nervous restem of the Jewi is race as a whol may play a part in this son litton as almost all of his patients have been temperamentally neurones.

The patients complain of disagreeable sensations in the feet and sometimes in the calves of the legiths increases to pain and is associated with a on gestion of the toes which extends to the dorsum of the foot possibly as high as the mail-oh

A dependent position of the foot aggravates this congestion and the pain is more severe and of a burning character the longer the foot is allowed to hang. Pain and congestion are appreciably lessened by elevation. Anterior and posterior tubal pulse is very feelle or absent. Congressions are an may be noted if the caliber of the vessel is sufficiently encroached upon

Pseudo-arthritides are quite prevalent among the Jewish people as described by Solus-Cohen A certain amount of apparently bons fide capsular thickening gradually develops even in these purely functional or neurotic joint disturbances. If such actual physical changes can take place in and about joints as the result of a non inflammatory condition the author advances the hypothesis that given the a tivity of a similarly duturbed nervous mechanism in the peripheral vessels of the extremities one might expect to find these vessels occupied by a thrombus while would attach study for the walls and organiza, into come tive tissue thus narrowing or occluding the lumen of the vessels.

The author is in favor of conservative treatment rather than amputation especially in the early cases. This treatment is resists in rest, elevation of the limb combined with keeping it well wrapped in cotton wood discontinuing the use of tobacco alcohol tea etc.

This necessarily means a long technis treatment but with sufficient means or hospital facilities, the end results justify the sacrifice of time

LUCIAN H LANDRY

Lindeman E. Reactions Following Blood Transfusion by the Syringe Cannula System J

Lindeman states that the syringe cannuls system has greatly simplified the procedure of blood transfusion which now occupies a prominent and permanent place in therapeutics. In the first 150

trui tusion by his method chill followed by there occurred in approximately 33 per cut. He had found that himmly is ne or occurre without hill in lever unless the patient his luring or hardly after the transful on H. inter there fore that chill and fever in transfulson are by to heaving bloom et tree in the circulating bloom! If the him glot met tree is abundant it appear in the urini when the amount is moderat hammly prephyring pay in the urin when hemoly is is hight in bloom trigment appears in the urin.

In this series of the cases, the priming in 11 say for heart has and aughturant in error in ducted by this rent say logic. In very, so in which has moly is securred and my high primingary test had been in the Landeman high the test in peat it later and in the hand earning in Hendith there was error in the primary examination and has set hims lit the task it limitating, this error by personal supervision the laboratory work and it is oping refined method of divitions of so privent even a slight degree or harmly us of which the only manifestation is bills and the

His technique for testing it hæmoly i and agglutination a e.a. follo v The red blood c ll f the patient and d nor are wa hed three times with normal saline variable quantities if pati ni s serum are placed in three separate small test tubes to each of these are added o s ccm of a pur cent suspension of washed blood-cells of the donor The same is done with the donor's serum and the patient's cell. Controls are made of donor's serum and donor's cells-patient's serum and patient cells. Controls are also made with donor's cells in normal salt solution and nationt a ells in normal salt solution The total volume in each tube is raused with normal saline to o s ccm of volume The test tubes are incubated in a water bath for a period of two hours, and readings are made. They are then set in the ice box over night and readings are again made the following morning. When a case is urgent the ice box test is eliminated

In the last 155 transfusions performed by the syringe cannula system with personally supervised preliminary tests no case of hemioly is and no death referable to transfusion occurred. Chills followed by a rise in temperature occurred in sixteen is stances. Adults received from 1000 to 1800 ccm in each transfusion and th quantity enumerated was always taken from one donor. No foreign substance or anticoagulant was employed in any case.

In the syringe cannula method of Lindeman the entire mass of blood is outside the body for a period of from six to ten seconds regardless of the amount transferred. It pa ses through a minimum amount of foreign material Embol m or clotting never occurs in tran it syringes are cleaned as fast as used. Clotting in the syringe can not occur and the blood is tran ferred unliquired exactly is it exists in nature. There are n stopcock val evo

rubber t bings about which blood may cl t and there is no blind system into which air may leak

His conclusions are as follows

I The preliminary hemolyti d aggl tination tests when properly performed are rehabl

Incidents of hemolysis in transfusion can be eliminated entirely

3 The eactions which if II w transitusion when ccurat test re mad are eliminated in all except 0 per cent of the cases. In this 0 pe cent chills and fever alon occu when the quantity is 800 ccm, or less chills and ever d not occur.

4. By careful, ccurat and complet hemolysis a d agglutinin tests when work is door skill lly blood-transfusion is robbed of all danger attending fix use

AL

Cherry T II and Langrock, E. G. The Relation of Haemolysis in the Transfosion of Bables with the Mothers as Donors. J. 4 m. H. 1 o 6 levi. 626.

Cherry and Langrock consider that hemorrhagid disease of the newborn is one of th most freque to a larming of the diseases in combating which translation is required. The boutaneous injection of animal or human serum (Weich) or of whole blood (Schloss) has been used with a consair ruble degree f success, but there have also been great many failures. The translation of blood bowever has given highly gratifying results

On account of the close relationship of the maternand fortal bloods tere it is natural supposition that complete compatibility of inf. t. and mother' blood should exist. In order to cet this this fact, the authors have performed a series of hem lyick tests in 3.4 instances, po newborn habit and their owners there. If the properties of his properties in the compatibility of the compatible is all save delay in fonding a compatible done in making the necessary serological tests, and in the expense which these conditions ent.

I the 34 tests carried out no harmolysis or sget tination occurred. Accordingly the authors conclude that all mothers can be used as donors for their infants in the transfusion of blood, provided no contra indications exist on the mother's part.

The others report one transfusion performed amere these experiments were concluded in which, without preliminary blood tests, 60 ccm. was successfully transf red from the mother through the external jugular vein, by the indirect syringe products of Unger They estimate that 60 - 73 ccm. are sufficient to supply the infant with necessary elements I promote clotting and I replace those lost by hemorrhage. They recommend the indirect method for its simplicity. Assert Denzirarian.

Rous, P., and Turner J R. The Preservation of Living Red Blood-Cells in Vitro; Transferior of Kept Cells. J Exp Hed 9 6, xxIII, 59.

Having described in a previous paper the methods whereby red blood-cells may be kept intact for

I g periods is sit. Rous d Turner have under it. 1 determine whether ells kept coording t these methods were alive in the sense that they are capable of functioning in the animal body. The they have attempt d t determine by transituon 6 the kept cell in bolk with appropriate cont of. They ha performed many such experiments, using bilts.

I order t determine the tronal uses of red ells kept the standium experiment wer tried out with rubbit by which large part of their blood was replaced with kept rabbit cells suspended i Lockes solution. It was found that rythroxytes preserved

mixt res of blood sodium itrate saccharose, and a ter for 4 days nd used to replace normal blood remained i ci culation and functioned so a ll that the nimal showed dust rhance and the blood court hæmogloben and percentage of reticulated red cells remai I un ried Cells kept for longer periods, though intact and apparently unchanged when transfused soon left the ci cula tion. Animals in which this disappearance of ells took plac on large scal emained healthy save for the progressing anamia. The experiments proved that in the exanguinated rabbit at least t anafusion of cells kept for a long time in rit ould be used t replace the blood lost nd that when the cells had been kept too long but were still int ct they were disposed of without harm. The indications are th thors at t that kept human ells could be profit bly employed i the same w y

BLOOD AND LYMPH VESSELS

Eccles, W. M. A Clinical Lecture on Aneurisms of War Wounds. Am J. S. g. o. 6. 13.

Eccles lastifies so cases of traumatic aneurism of emphasizes some points in regard to thelter timent. Of the 50 cases, 30 were arterial and 20 were arteroscopia, 7 were of the vessels of the head od neck, 4 of the vessels of the upper extremity and 20 of the vessels of the lower extremity. The poptited suffered more frequently tha any othe vessel. There were 4 deaths in the series.

The signs of traumatic ancurisms vary somewhat from those of pathological neurisms. The bruit is usually much more marked and the thrill is harsher Where the clot is large the pulsation bruit and

thrill may entirely disappear

With regard to the treatment f traumati ance runs in general the author makes the following suggestions. (1) Delay operation as long as possible in order to all w time for collateral circulation to be established. (3) Always be prepared? produce harmorrhage. (3) Mak long incision in order to secure an abundance of room.

The methods of dealing with traumatic aneurisms are three ligation of vessels, operations on the

sac and amoutation.

The application of ligatures to the artery on the

proximal and distal sides of the aneurism is quite the best method of treatment. A ligature on the proximal side alone is uncertain in its results and may not control the bleeding. The ideal method of treatment is to apply a tourniquet open the sac pass a probe into each communicating v-sel and ligate each one externally but it is not altogether easy and causes a good deal of disturbance.

Amputation is required if gangrene has set in and may possibly be the safest as a primary treatment where there is a diffused traumatic arterial anguingm

Quadruple ligation with excision of the intervening portion is the best method of treatment in arteriovenous aneurisms.

J W TURNER

Haberland, H. F. O. The Epicrises in Wound Aneurisms (Zu. Epikinse der Schusssmeury m. Drut keined II. km. kr. 1016. Mit 100

In the case of traumatic aneurisms of the extremities it is only permissible to speak of a cure when complete functional use of the organ has been restored and provided there is no serious secondary injury.

Great caution must be observed in making the prognosis owing to the danger of late gangrene developing observation after operation should be continued for at least six weeks

Early vessel-auture is favorable to early recovery Oval auturing is to be preferred. Arteriovenous aneurams ought always be operated upon on ac count of the danger of embolism. Conservative treatment will not effect an anatom cure.

II I BRENN A

Judd E. S. Cirsoid Aneurism St P wl M J 9 6

The author reports quite an extensive case in volving the entire forehead in which there was a large mass over the bridge of the nose which extended into the right lide, entirely closing the eye The dilated vessels passed back through the sculp to the occipital region. The right facial artery was considerably dilated as it crossed the border of the issue at the anterior border of the massiter muscle.

Under ether and local anesthesia, the right external carotid was ligated as well as the facial just above the submaxillary gland. The publishion was considerably diminished in the prominent part of the angioma, but in a few days the condution was the same as before operation.

Six days later the opposite external caroud was higated which practically stilled the vessels. The patient was comfortable for a few days, when the skin of the scalp over the aneurann became tense red and extremely painful. The scalp and tissue about the face were very sensitive. The pain was obgreat that morphine had to be administered.

Five days later the scalp was incised from the glabella to the inion, down to the periosteum. The scalp was reflected on both sides and the dilated and thrombosed essel were dissected out. There was no tendency to hæmorrhage or a treelleding. The scalp was sutured. One or two separate in 11 ns about the face and temporal region. It necessary and the essels in these rights extrapated.

LUCIA H LA DRA

Knettner H Experience in Injuries of the Large Blood Vessels in War (Mei Erfahrungen in der Kriegschurgere der grossen Bl teef esssta mme Beil klis II k k vorf hill. t

Kuettner's experience with injuries of the larger vessels including aneurisms is based upon 40 cases in the Graeco-Turkish South Mirican and the present wars

Next to nerve injuries ancursing are the most interesting to the surgeon. These classes of injuries give the greatest contrasts in peace and war. In visicular surgery, however unlike surgery of the nerves the surgeon can see the success of failure of his intervention at once without having to wait an indefinite period.

Injuries to the large blood vessels are so serious and the operators difficulties so great that their treatment should be left to the most experien ed and skillful surgeons. Kuettner classifies blood vessel injuries in three groups (1) injuries with external hæmorrhage (2) injuries with internal hæmorrhage (2) injuries with internal hæmorrhage and (3) complete aneumset.

Regarding external harmorrhages kuettin r states that the percentage of soldiers who die from harmorrhage on the battlefield depends on the kind of battle and the class of weapon. In artill re wound fragment of shells and apenally pieces of teel grenades cut through the vessel like knile nd there is a large external hemorrhage. The crushing effect even of the large modern projectiles counts for much less than the fiects of splinters.

Ancutama are more frequent with the present day jacketed bullets than formerly. The small en trance and exit wounds make it more difficult for the blood to flow. Regarding treatment of hemorrhage in the field the thors states. In remove, the small present bullets are usually sufficient. Ligation is rarely necessary. In arterial harmorrhage in about half of the cases, ordinary means—clother of parts pressure bundage t myon means—clother of the state of the cases, ordinary means—clother ordinary means—clother of the cases, ordinary means—clother ordinary means—

When the firing is at close range death from hemorrhage is more common. Regarding aneurisms, they rarely result from grenade spit ter or shrippael wounds which are likely to be f tal. They are rare in wounds from jacketed bullets with fracture of the large bones they occur only occasionally

when the entry and exit wounds are larg Secondary hem rinages re even more important than primary. These may be the result of infection (septic croid in) or a spicult of detached bose may injure the result of it may be due to pressure of a drain in the vicinity of a vessel. It is to always noticed until the patient a coodition in serious. If these secondary hismorrhages are frequently epeated amputation may be called for if the secondary hismorrhage is from a main arterial trunk which is budly infected amputation is the best

course as suturing and ligation is out of the question.

The a tho has found vast benefit in parenchymnt our aeptic secondary hierorrhage from I travenous.

injections of congulen.

With regard to internal harmorrhages, the author states that hematomata are usually present in all war injuries of the larger vessels. They show pulsa tion. Where a vein is injured arterial blood for quently finds its way directly into the vein causing an arteriovenous fistula and the f rmation of harmatomas is small.

Diagnosis fhematoma is nually easy but it may be confounded with abscess. On account of the possibilities of perforation, infection o gangrene of hematoma, and the fact that spontaneous healing is infrequent, the author thinks active early surgical

intervention is indicated.

Kuettner treated altogether 93 sneunsma, 56 of these were complet and 37 were in the hæmatoma stage 45 per cent were arterial 55 per cent were arteriorenous 73 6 per cent w re treated by ligation 36 4 per cent by suture. W A Baunnar

POISONS

Freeman L. Chronic General Infection with the Bacillos Pyocyaneus. T. Am. Surg. 4 Wash Ington, 9 6 May

The author gave a brief statement of the prominent symptoms of pyocyanic infection together with the main fact in its pathology and a somewhat detailed report of an instance of the more unusual chron form of the disease, of which only a few cases

hav been recorded.

The author's case was in adult, who had been III for nearly elever in inthe. He had a high fever of the sepile type eruptions upon the skin severe neuralgia, serous. If usons and muscular paresis and trophy.

D ring an exploratory laparotomy a cholecystostomy was done and pure culture of the bacillus proxyagenza ecovered from the black of thickened bile. From this s v came was made and administered to the patient foll wing which the patient gradually recovered.

The features of especial interest in the case are

Its extreme hronicity (nearly months)

The typical neuralgic pains, followed by pare

and muscular strophy

3 The absence of the bacilins procramers from the blood and its presence in the bile. (The germ does not grow in the blood but is merely conveyed by it lodging and mult plying the revel walls. It is found montly in the parenchymations organs, such as the liver spleen, and kidneys bence i par ticharity set to infect the bile.

4 The absence of any discoverable point of infection unless it might be the teeth.

5 Recovery following drainage of the gall-blad

der nd the use of an autogenous vaccine

6 The occurrence of cirrhosis of the liver 7 The presence I ascites and pleural effusion.

8 The satisfact ry recovery after so severe and protracted an illness, with the exception of moderat parests of the lower limbs, which seems to be improving.

Barling G. Remarks on Delayed Teran s. Brit H = J = 0.1, 337

Three cases are reported in which the incubation period varied from 50 to 53 days. In most of the cases the riginal wound had poparently bealed before the onset of tetanns. The cause of the prolonged incubation period is unknown siltough several theories are advanced. At least two of the patients reported had prophylactic doses of a fitetank serum, which may have inhibited the growth of the organisms on neutralized all of the t vin available during the first days after the receipt of the wound. In several of the cases a lowering of resistance seemed to precede the onset of the tetanna.

J. H. Srinzs.

Abercromble R. G. The Treatment of Tetanus. Brit M J. p 6, i, 339.

Four cases are reported in full. The effectual daily dose would appear to be 10,000 t 10 000 units. This may be given twice a day in critical cases. The major portion of this dose should be given intravenously, subcutaneous injections being loo used to maintain the flect Intrathecal injections should be given daily or at guch intervals as the symptoms deman! The dosa e must be redu ed gradually in order t pre ent r lapse

All rill agree a. the desirability for i treatment of siled ound as a precent enteranus, but when once the listed has dellar it ell pera it et urn all intertiente with the surface, it the yound all the up to remembel several auch trutes is a problem a mannar of by considerable dance. Kuepferle and Bacmeister Experimental Gounds for Treatment of Lung Tuberculosis by \ Rays E perim itell (ru dl.gen fix di Beh dl. k der Lunge t berk lose m.t. R. tge i hl De is hum dill hesch 00 1 00

The authors in tituted a series of experiment a let roune the effect of hard thered X ray experimentally produced lung tuberculous in r l. The conduing which they draw from these but experiments are that a beginning sperimental tuberculosis of the lungs may be uppressed and an established tuberculosis may be healed

The effect of the raying is to transform rapilly growing tuberculous granulation tissue into acatra cial tissue. It has no effect on the tubercle bacilly Small doses of rays at long intervals have little effect very large dosage without ufficiently long reaction intervals, may give rise to bronchiti and bronchopneumonia

In animals a dosage of 20 to 23 at 3 to 5-day intervals effected healing. The mercury lamp had

no direct influence on lung tuberculosis. On the basis of their experimental finlings the authors have introduced \ ray therapy for lung

tuberculosis in the Freiburg Medical Klinic W. L. BREN A

Hammes and Schoepf Exact Localization of Foreign Bodies by Means of Roentgen Rays (Zur genanen Localizatio n Fremdkoerpe n mittels Roentgenstrahlen) De is he med il hu h 10 6 xlil 35

The authors describe the technical details of an apparatus to put into practice results obtained from rertain mathematical equations which give the position of a foreign body located in the body. They claim that location can be obtained in a fe v minutes and that probably their method is superior to the many procedures described by others

Wintz, H and Baumelster L.: The Proper Filter for Deep Roentgen Therapy (1) eckmues go Filt d Rentgentlefenth rapic) Mu he md 0 0 l mi 30 II A MA

The authors made a series of experiment to d termi e what wa the best a terral and next

suitable thickness of a filter for deep roentgen treatments. Experimentation with various metals showed that the most favorable results were obtained with an aluminum filter 3 mm. thick and

with a zmc filter o 5 mm, thick.

To obtain an equal dosage on the skin with alu minum and sinc filters the exposu o in the case of zinc must be three to three and one half times as long as with aluminum but at depth of 8 t o cm the ratio is reduced to At this depth when using the thicker sinc filter by doubling the strength of the rays, the same dose can be received on the sain as with the thinner aluminum tilt r The advantage is that a dosage which with an aluminum filter would reach the crythema limit may be doubled by using a zinc filter The authors prefer the zinc filter to any other W. A. B LICKAR

Case, J. T. Roentgen Treatment of Deep-seated Cancer Physicia & Sure 0 5 XXTVII. 44

Case states that in general it must be admitted that the \ ray treatment of deep-seated curemoma has not up to the present time gratified the fond hope with which the discovery of this method was

so fervently greeted.

In superficial carcin ma where there is deep ulceration with involvement of the neighboring glands, etc., a very thorough-going preliminary preoperative roentgenization abould be administered. On the month or tenth day a radical operatio should be performed followed later by another \-ray treat ment By combining roentgenization with surgical intervention one is most likely to insure good results.

Discussing the question as to whether operable carcinoma shall be treated by irradiation or opera tion, Case states that the result which have thus far followed roentgentherapy of deep-seated malle flections d not warrant the belief that roentgentherapy affords a means of cure i these deep-scated lesions. In the light of our present knowledge it may be stated as an axiom that the I ray method hould never replace or in any way interfere with the surgical treatment of cancer

In looking over the literat re of competent authors it is seen that in about 25 to 30 pe cent of th cases futerine carcinoma, the results of roent gentherapy are very satisfactory from a palliative standpoint but as yet Case has not seen an instance of definitely proven cure of pelvic cancer following the application of roentgentherapy

In mammary carcinoma good palliative results

are nearly always the rule.

The good palliative results which have followed the \-ray treatment of recurrences and inoperable cases warrant the adoption of post-operative X-ray treatment as a routine in malignant cases.

The treatment should be applied as soon as possible after operation and as thoroughly as though the disease was still present in its entirety

Case a technique in operable cases is to submit the petient eight or ten days before operation to cross-fire filtered rays in full dose in as many areas

s possible. Ten days after operation the patient is gain submitted t a further series of treatments administered as though the tumor were still present HOLLES L. POTTER.

Hanford C. W. Some Radium Physics. Chicago 9 6 tx van. 43

that I tes that the burh aim of the radiotherapust should be to I rect the radium rays to th deel tissues where the disease is located with th least 1 jury t th healthy structures and that in many instances wher results have not been obtained from their apply tion, fallure may be tra ed to lack of kn 1 dge of ertain physical fact that had not been beeved by the operator A umber f examples re given, ch as where

Wood, F. C. and Prime F., J. Th. Action of Radium on Transplanted Tumors of Animals. Surg Phila o 5 ltm 75

The opnions, based chefly o chalcal reports, of the ther peutic value of radium in the treatment of malgnant growths have differed greatly Whether the \$\beta\$ or the \gamma\ rays re the most efficient in treating tumors, or whether both should be mix yed re q entions still undecided. For these

othe reason the authors carried out number perunents in the Col inbia University t deter m ne the bi logic action of radium, using animal 1 m rs as index of the lethal effect. R t and m se tumors I variou types were used among th m th Lhrlich pladle-cell mouse sarcoma and the FI vner Jobling rat carein ma. They were t ated either afte remo al from the host or i situ strict asepula being barryed. After exposure to the β - od γ rays, portions of the treated tumor as well as untreated fragments were inoculated with animals of the same strain. A rays were not used.

These results re claimed by the utbors from their experiments

Three factors only are important in the action of radium on tumors time of exposure amou t of the radium element and distance between the radium the nd the tumor time. 2 The removal of the β -rays diminishes the

effect of the radium but the effect of the 7 rays is in ccords ce with the same general law which governs the B-rays.

3 Sublethal exposures binder the growth of tumor cells for some time, while still shorter treat ments seem to stimulate the cellular activities.

4. The facts derived from the experiments regard ing the quantity of radium element and the time of exposure necessary for a given distance may be applied, with reasonable accuracy to human malie

nant tumors. These experiments how that when only pure y mys are used the necessary exposure is eight times as long as that require 1 + 0 in the γ and hard β -rays combined are mplied but is the latter are largely absorbed 1×1 to tissue the γ rays alone must be used for all d α by work

5 The effect of radium radiati i on timor-cells in titro is less marked than on isol ted of littlar elements. This explains the fact that an sposone which will distroy a small metastati. In adule in man is quite ineffective in the case of a will asculinized primary carrenoma.

If LEIS E I TILE

Quigley D T Therapeutic Effects of Radium.

Quijley thinks that in ordinary cases of cancer such as cancer of the breast etc. the best plan is to operate whin operation is possific and use radium as an after treatment to kill out on the cliss as may be missed by the kinde and thereby lessen the chances for recurrence. He believes the great future for radium is as a post-operative treatment. The question with relation to radium in can er is not. Will rodium supplant surgery in these cases? but Will our surgical results be bettered by using radium in conjunction with surgery.

HOLIS E POTER

McConnell A A A New Medium for Pyelography

Md Priss & Cure o 6 d #36

For some years collargol a colloidal silver preparation has been the medium most used for pyelography and although other substances has e-been tried as noticed of silver none have proved so gen

erally satisfactory

Since the war however collargol has become most unprocurable and McConnell in seeking a substitute in the English and American markets, failed to find anything but silver lodide which in his hands did not give as satisfactory results. He therefore consulted Professor Caldwell of the Royal College of Surgeons Ireland asking him for a salt opaque to \ rays harmless to the kidney, and capable of being injected through a ureteral catheter Professor Caldwell was able to meet this request and supplied him with an entirely new bismuth compound to which the provisional name shirol is given. This is a non irritating substance, has the consistency of milk and is washed out of the renal pelvis by the urine before precipita tion takes place McConnell uses a 10 per cent solution and has obtained better pictures than any he has obtained with collargol. It has not caused irritation in any of his patients. Moreover he found that it disappeared from the pelvis more rapidly than collargol Collargol has been found to remain in the renal pelvis from one to several weeks while in some cases in which skirol was used radiographs taken one or two days after the injection showed no shadow

The technique is as follows The patient is placed on the roentgen table the ureteral catheter is

introd i of up to the renal pelvi. the N ray plate is a fin ted and preparations and to take a pic ture. The skirol solution is then allowed to flow into the ureteral catheter by gravity from a continur riwh is he li not more than is in hes above the left of the kilney until the pattent autounces that win pain is tell in the kilney. MILITARY SURGERY

Mott F W The Effects of High Explosives upon the Central Nervous System Lascet Lond

The author describes three groups of cases in which the nervois stem was injured by explosives (i) immediate death from a missile () injuries from high aploanes which cause wourds but are not fatal (3) injuries of the central nervois system without visible injury. To the latter group must be added those cases with develop functional neuroses and psychoses.

The third group of cases is the one specially dealt with in this paper. Several theories are elaborated as to the possible causation of these intargible injuries to the nervous system (1) Interaced pressure in the cerebroapinal fluid may be the causative factor in these injuries (2) N rec-cells in a state of ethouston are much more asseptible to shock than nerve-cells in the normal state. This fact may account for sudden death from the splosion of a shell without physical injury (3) The sudden change in atmospheric pressure brought about by the explosion of a shell may result in the freeing of gas bubbles in the nervous tissues, ausing a similar condultion to that found in cusson disease.

These theories are merely advanced by the author in a preliminary way and the discussion is to be continued. I II Skiles

Vincent B and Greenough R B: Gunshot Wounds of the Soft Parts. Bosto M - S J 19 6 clear 155

Vincent and Greenough at the American Ambu lance, at Neuilly sur Seine report 318 cases of injuries of soft parts by missiles such as shrar nel balls, rifle bullets or shell fragments. The wounds were of every kind la crated penetrating perforat ing or wile surface abrasions. When received at the American Ambulance a majority of the cases were from twenty four to seventy two hours old and were with few exceptions septic. On entering the bospital the patient was given a general anasthetic. The operation was devoted primarily to cleaning the wound and making free dramage The wounds were enlarged as much as the extent of the infection required. The crushed edges of the wound and all the necrotic tissue were excised All foreign material was removed. While in particular search was made at this time for misules, for fee of spreading the infection to uncontaminated tissues, they were often discovered and removed Pieces of clothing were often found just beyond or wrapped around the misule. When pieces remained in the tissues the course of septial was also ys prolonged. The use of rubber tissue for wicks and as a protective covering f r raw surfaces prevented the gause direstings from distring to the wounds of several the patients much suffering soon of the moons of sections were given continuous limits of sections of sections and the section of sections with property changes. See ondary sutteres were done with good result in cases with extensive granulation surfaces.

The means of localization most frequently employed were the fluoroscope \ ray plates and the Bergooler electromagnet. The magnet was oper ted with an alternating current i such a way that the shell fragment was put into rapid vibration. By placing a hand on the skin between the magnet and the foreign body the place of maximum vibration was noted and an incision made at that point. The method could be applied t missiles in the soft parts only nd not too distant from the skin. The extraction of a missile was often facilitated by the use of an ordinary electromagnet. A metal probe with it outer end resting against the magnet was inserted into the wound till it touched the piece of m tal The magnetized probe would in turn ttract the missile which was withdrawn with the probe from the wound. This method was employed uccessfully by Cushing in removing fragments of shell from the brain and by Blake on a piece of shell buried deep in the pleural cavity

For routine work the fluoroscope proved the most rapid accurate and economical means of localizing lodged missiles

In certain cases where the fragments were small and numerous or because of an absence of symptoms, the missiles were left sits A. H. Hexson

Weinberg, M. Bacteriological and Experimental Research on Gas Gangrene Lancel Load., 9 6, crc, 6 2.

The work reported was first undertaken in the British Hospitalst versiller. Soptember 1914, during the battle of the Marme, and was conducted later in a number of bospitals, both French and British. The majority of surgeons seemed the have a confused idea of the nature of gas gaugene at the beginning of the was and the tendency seemed to be to diag nose the condition every time a bad wound became infiltrated rapidly with gas. Two forms of gas gangrone are described () the classic and () the toxic form.

In describing the classic form the author gives the details of a case as follows. A soldier was admitted to the hospital twenty four bours after being wounded. The foot and two-thirds of the leg were very much discolved the discharge emitted a putrict oder. The leg and thigh were swollen as far as the junction of the middle and pper third, the veins were distended the skin bronzerd, and the was crepitation polyation around the was crepitation rended over the entire gratient attention at the continuous conti

The development f some axes of this classical form was not lawrs as rapid as in the foregoing case because the microbe heely ins crable was of low degree of pathoge selly and in such mild

ases radical urgery often saved the patient The toxic form I haracterized by extensi cedema sufficent in some cases to mask the gradu filtrat n This form i ill strated by the follow ing use \ par ent w dmitted t a French hospital f rty hours after be was ounded, ha ing been sposed twenty fou hours bet een the French nd Germa lines feer the receipt of the injury There as a wound i the m dell third of the fore arm to cremit to around the wound was slight but extensi v redema was present up to th middle of the arm and the erm were prominent In spit f free inchions and irrigation with oxygen peroxide the cedema extended t the shoulder and chest and death occurred twenty four hours later without the appearance of much crepitation. There was a putrid odor which was not necessarily s symptom of the case and it bore no relation to it gra ty since it might have been due to organisms

fal w pathogenesis which were present.
The uthor exhibited some microphotographs of culture facis from cases which showed a warlets of organisms, including bacilli perfringers, staphy lococci streptococci and diplococci also bacillus spropenese.

It seemed that gas gangrene was not due to my one specific micro-organism. There is great dif ficulty in distinguishing bacilles perfringens from vibre stplique (malignant ordema) and the toxins must be tested with antitode serum. Bacillus perfrigens produces a large quantity of gas while ribra sell que produces less. A bacillus cedematis had also been found in some cases, the tonins from which when injected subcutaneously in guines pigs produced a rapidly extending cedema. This microbe was frequently associated with bacilli sporogenes, Weinberg emphasizes his belief that there is no fora peculiar t gas gangrene. A new microbe bacilhus fellex, causing gas gangrene has lately been discovered, when and by whom is not stated. Some of the organisms found in the flora of gas gangrene emanate from the air others are of intestinal origin Attempts to make hemocultures have not been suc censful and they were rarely positive in the septic form of the disease. The very rapid course of gas gangrer in men and animals is thought to be

due to individual susceptibility. Careful observa a time and experiment have shown that gangeries of a limb is not always the result of gas-produring organisms but complete obliteration of the vessel may arise from non-gas producing organisms. It is interesting to note that gangeries. I a limb following stoppage of the blood supply allor! favoral le conditions for the grawth of gas-try lucine microbe.

To prevent ga gangrene wound huld be treated early and radi ally. The diminution in the number of cases occurring n as compared to the earlier period of the war is due to the well developed tran port farilities which hable the relief corps to remove the wounded from the fight ing front to asualty hospital in a few hours wounds should be opened a writely as possible at once. Large projectiles and particles of clothing having been removed, the wound should be ignerated with weak antis price and the impation should be often reneated. Good results are also obtained by the use of superheated air and intravenous intetions of sal arean. Injection if polyvalent serum made from all the organisms concerned was also on ther I helpful

Moynthan B The Treatment of Gunshot Wounds. B t If f $g \in \{33\}$

The treatm at figurahot wounds in the present war has become greatly complicated by several factor (1) The wounded soldier usu lly lies for many h urs or ev n days before he an be removed to the neld hospital (2) The mod in high velocity projectile causes explosive destruction of tissuresulting in a large leep ragged wound which is alway intected (3) The battlet elds have been so int usely ultivated that the ground contain many virulent organisms with which the bodies and cloth ing of the men re sure to become contaminated (4) The hygiene of the soldier is necessarily very poor. In some instances clothing has been worn c ntinuously for several months. This results in a filthy condition of the person which together with his general run down condition naturally leads to ontamination of the wound

The treatment of a wound therefore usually has to do with the combating of infection. A wound which is treated early may be excised or treated with some strong antiseptic but these early wounds

are in the minority. The treatment of an infected wound should be very thorough, the entire field being thoroughly cleansed and adequate drainage secured. Many antiseptic solutions have been tried the one which has given the most satisfactory results being Dakins solution. Dakins solution is made from bleaching position of Dakins solution is made from bleaching powder forming calcium hypochlorite. It is a very effective antiseptic and does not apparently injure the tissues. Continuous application of the fluid to the wound is secured by continuous irrigation or by keeping gauze wicks soaked by immersing the ends in a dish of the solution. Sufficient drainage should be insured.

No gauze dressings or impermeable material hould be placed over the wound as a close overing tend to dam up the secretion

In hypotonic salt solution of Wright i highly remmen led to induce lymph large. Morrison in I fullock have advised the use of a solutin of magn-nium sulphate in place of sodium chloride Out-door treatment and plenty of fresh air it in work wonders in hastening the recovers.

The use of a cines is still a mitter of ontroversy but there are und ubtedly selected asce in which they do much good. J. H. Skir

Carrel Dehelly and Dumas Secondary Closing of Wounds B t M I + t

The auth r presented a paper at the Pan-Acalemy of Medicine in Januars in the result is the early closing of war wound that have ben treated with the sodium hypochlorie solution; repar a latter the Dakin f rmula. They in luth that the secondary losure of wounds in from ture to the fasts at general method of get to.

Free incision of a unids a lone trimets for exploration the removal or torigin matter and the use of drinings act as a drawba k incusting Trolong the treatment and alone an undue amount of a attraction. The latter fill the pares between the muscles apponeurous and kin which ends in adhesions and outractions ther by him kring function. To avoid this treatment by the Dakin solution permits the surgeon to bring the anatomical surfaces of a wound together by layers in the secondary closing of the wound jut as he does in a primary operation. When brought together early connective this use has not had time to form unduly it is reduced to a thin sheet which does not a rousily interfere with muscular movements.

The authors open up all nounds primarily enough to admit of careful exploration cleansing and The hypochlorite solution is instilled constantly for several days by the technique already recommended by them in previous reports soon as the daily bacteriological examinations in licate the disappearance of bacteria the wound is closed usually in four to ten days. In those wounds that remain uninfected the tissues are un altered in the course of the antiseptic treatment and the authors and that the wounds thus treated unite by first intention as is observed in operative wounds. The ressues should always be brought into exact apposition with adhesive strips 25 to 5 cm broad If the skin becomes adherent to the subjacent structures and granulation tissue has filled the intervening space the skin is loosened from the edges of the wound the granulations curetted and the parts including the skin are then brought into apposition with sutures This procedure hastens the rate of recovery avoids stiffness and atrophic changes

M Qu nu and M Bazy believe that good surgical technique and irrigation are of more importance than the employment of sodium hypochlorite as an autiseptic L. V. L. Cup.

Bérard, L., and Lumière, A. Some Elementary Rules Relative to the Treatment of Supparating Wounds in War (Quelques préceptes élémentaires relailis traitement des plaies de guerre supparées) Re de la ri 19 6, xxiv 445.

The authors call attention to the difference in the condition of projectile wounds in the recent period of the European campaign, where the fight ing was in the trenches and that of the early period when the war was one of movement and projectile

wounds were mostly uninfected. The suggestions which the authors formulate in the care and treatment of suppurating wounds are (1) the removal as quickly as possible f all foreign bodies () the draining as early as possible of infected tracts, nd the discharging of purulent collections by large incisions and very large drains (4) the treating of all wounds ntiseptically using hypochlorites preferably especially the musture I chloride of lime and boric acid (4) the frequent changing of dressings and preventing the adhesion of pieces of the dressings t the wounds (5) never to uselessly injure wounds (5) to use humid dressings only occasionally in particular cases renewing them quite frequently A. Cont.

Dalton, F J A Sodium Hypochlorite in the Treatment of Septic Wounds. B st. M J 0 6 l., s6.

Dalton on the British hospital ship Rew investigating the value of sodium hypochlorite in the treatment of septic wounds, reports a series of 57 cases. The results obtained were uniformly excel lent and there was an absolute unanimity among the members of the medical staff in the hospital ship in the preference for hypochlorite solution in the irrigation of infected wounds. Wounds were en larged, counteropenings made, bone fragments a d foreign bodies emoved etc. and thorough irrigation instituted with large quantities of hypochlorite solution. Rubber tubes were then inserted and ganze strips packed into all parts of the wound. The ends of the rubber tubes were brought out through the dressings that the hypochlorite solution might subsequently be renewed by means of a syringe. Fresh hypochlorit solution was applied in this way every two bours in the severe cases. In the worst cases the gauze strips were removed after twenty four hours, in slight wounds they were left in three or four days, the wounds cleaning up with simply spraying fresh solution into the tubes

Dalion points out the following advantages observed in the employment of the sodium hypochlorite solution when properly prepared coording to the Dakin formula () The amplicity and cheapmens of preparation of the santespile. () Being non-toric and non-irritating to the startes it may be used without ill effects in large quantities over long periods of time. (3) The decolorant action of the solution is remarkable. (a) The nightly with which slonglasseparate and clean granulation these is formed. (5) The infrequency of dreading required. (6) The

f et that injecti ns of the hypochlorite solution into the rubber tubes used in the dressings may with saf ty be entratted to very imperfectly trained or derites without fear of ill esults, once the case has been adequately dealt with by the surgeon

Health of Armies in Peace and War Lancet Lord, 0 6 cz 5 7

The annual report of the Surgeon General U.S. I fro 4 pt es us a shable means of comparing the health fran army luring pence with that fithe arms to will be upon the Although the army is usual in comportion with the armies engaged in the gips the struggle abroad it is sufficiently large to give valuable dat.

Of the 83,000 mm 4 dt d of t bertulosh 13 erch from proumons in I chronic heart disease, of om neer—ratios which correspond with those of other armset during years of peace. The influence of 'accinate gainst smallpox and typhoid fever is did hot whom give 83 000 mm there were grases of mallpo with e death and 3 cases of typhoid fever is the no death.

The principal causes of dimission to sick report were alcoholism and venerral disease although these are showing marked diminution in the last decade.

The Paris correspo d to the Lon t in a recent letter writes on the sack rat f the F each army at the front a d show that the mo e seriou infections diseases of ci il life such as scarter fever and diphtheria, as well as m mps and less important subments, are not so per sheat in the French army

during peace. Typhoid has been more frequent but less f tal. No ref ence is made to the various pecial aliments of the present w -shell shock, soldier's heart tench foot—nd they may be intentionally mitted. The inference seems to be justified that the health of the French rmy has not been adversely influenced by the act of campalening. Doctor Mosse of Berlin, a thor of a well-known work on disease and social position has recently pointed out that dubetes mellitus and cute nephritis, often of the hemorrhapic form, are more frequent in the youthful combatants. The health of rmies in peace and wa has been conserved by the rules of sanitary science in all civilized countries. The devast tions incident to cholera cerebrospinal meningitis, typhus typhoid, yellow fever and malaria are now practically unknown. The sanitary service of the military establishments today is rendered efficient by drilling the medical personnel in the duties of health officers. It is easier and less expensive to prevent disease than to treat it or to arrest its spread. In this regard the Sanitary Service of the British Army has accomplished a great deal in the present war. Every division of the army has a sanitary section consisting of 26 men (not including army service corps men) viz. one off cer and 5 non-commissioned officers and men. The officer is generally a medical ficer if health

or one who holds a diploma in public health service or as a bacteriologist some are amitary engineers and even architects.

A large number of the non-commissioned officers are saturary inspectors, some hold satur try diplomas others are plumbers carpenters schoolmasters graduates in honors from Oxford Cambridge and other universities solicitors chemists, and represen tatives of all professions and trades In this varied personnel it is not difficult to provide each section with a sufficient number of disinfectors interpreters carpenters cooks builders for the special and varied services in the field. The work performed by these sections includes the bathing of troops by thousands disinfection of the men for vermin after entence cerebrospinal fever and other infectious diseases Their further duties embra disinfection of all clothing and blankets purification of water the drainage of farms and billets gaying instruction for the erection of destructors or incincrators, ablution tanks grease traps urine pits filters fly traps and the installation of every kind of structure or appliance that apperture to sanitation in the field

After great battles, when the casualties are so great in numbers that the ambulances cannot deal with them the personnel of the sanitary companies is called upon to assist in the care of the injured. This body of expert workers has rendered the Royal Army Medical Corps officers valuable assistant et a many wars especially in watching over the health

and sanitation of the soldiers

Asside from the work of the medical orps and santary sections in warding off decises great assistance has been derived from auxiliary bodies like the Red Cross. Through its assistance the mortal ity among the wounded has been very much reduced since its organization by Henri Dunant a half century ago.

SURGICAL PATHOLOGY

Razetti L.: Operative Mortality (La mortalidad operatoria) Ga med de C racas 19 6 till 17

The author reports the results of 110 operations performed during a period of 22 months. The cases were divided into the following groups head neck thorax abdomen genito-urnars apparatus perincum and rectum extremities.

Of 310 patients operated upon 30 died a mortality of observed. The general mortality in the surgical clinic was divided into two classes the pathological mortality and the operatory mortality, or those due to accidents or complications derived directly from the operation itself.

Of the 10 d aths 16 were pathologic and 14 operatory or a pathologic mortality of 5 16 per cent and an operatory mortality of 4 5r per ent

The cases occurred in a general hospital the cases were in t selected and some of the cases were in an advanced stage or their general condition on ad mission was very unsatisfactory

peritoneal attack associated with urticaria

W. A. Bri. N.N.

Gaucher Unrecognized Syphillide Leaiona Sur gicully Operated as Cancera or as Local Tuber culouls (Des 1 vo. syphilly) or mr. un operess cruspy above t. mm. a. no. emm. t. be c. lose-1 to. leay. 1. mal. i. n. lar. v. b. 5.1

Theoretically the differences between stylhittic tuberculous and cance out brinns appear to be so well established that in practice there hould hardly be an error. Neverthiless the diagnosis is some times very difficult or at least it is very inexactly made in a number of cases by surgeons who are experienced and well informed. Errors are ofteness observed in chair resignmentous inditrations and in osseous and articulation leavors.

The confusion of syphila with local tuberculosis has very grave consequences part utality when it is a quistion of osseous or articulatory lexions. The author has frequently direct attention to the similarity of the supportant ostellis and the osteo-arthritis of hereditary tertuary syphilis and tuberculous outerists and arthropathies supports toon is not and cannot be admitted to be a distinct characteristic of tuberculous. Hereditary osseous syphilis can be suppurative as well as osseous tuber culouis.

Not alone in the matter of hereditary styphuls ar errors made but also in the white tumors in adults which result from acquired syphilis and which are frequently treated as white tuberculous tumors and operated as such

The author mentions several cases which have come under his notice which corroborate his contentions. He therefore thinks that in all oiscous or articular lesions which are apparently of tuberculous origin the Wastermann reaction should be looked for and mercunal treatment tried before surgery is resorted to.

HOSPITAL, MEDICOLEGAL, AND MEDICAL EDUCATION

Th Duties of Medical Practitioners in Cases of Criminal Abortion Brit M J o 6 i soo

The d ties of medical practitioners in cases f criminal bortions are discussed in the original article. The question as to h w far a medical man, who obtains in his professional capacity knowledge of the commission of a criminal fience, is in duty bound as citizen to give information t the police authorities and so set the criminal law in action, is one which should be of great interest to the medical profession.

Probably the most frequent occurrence in which an opportunity of this kind might arise, is that of medical man called in to attend a woman upon whom an illegal operation has been performed and in such case under the decisions of the English Court cited in the article it is safe to say that the doctor is under no obligation to and indeed should not divulge the inf rmation which he has obtained in his professional capacity as it is of the highest importance that professional confidence should be respected and held inviolate. Quoting from an English case I doubt very much whether a doctor called in t assist woman in procuring an abortion, i r that in itself is crime but for the purpose of attending her and giving her medical dvice could be justified in reporting the facts t the public prosecutor There might be cases when it is the obvious duty of medical man to speak out and it would be

monstrous thing for a medical man to screen serson going t him with wound which it might be supposed had been afflicted in the course of deadly truerie. The above is a quotation of Lord Brampton remarks before the Royal College of Physicians of London in 806

In 1914 the English Courts had t deal with a case of an alleged illegal operation on a woman on whom three successive doctors had been in trend nce None of these doctors had given information to the police and there was consequently no evsie ce pon which t co vict the prisoner wh was charged with baying perf rmed the illegal operation. The part in ducum g the failure of the attending physician to report the matter stated. No one would wish t see dist bed the confidential re latso which exist between the medical man and cases, and it appears to his patie t but ther m that this is on whe the desire to preserve that confidence mu t be subordinated to the duty which is ast pone erry good citizen to assist in the vestigation of MR Time such as is here imputed to the mai. It may be the moral duty n ases where the patient of the medical ma not dying or not likely t over to communicate a th the th rittes when he sees good reason t becrimin I offenc has been committed he that The tre d of the bo lecrato will be noted t be somewhat contrary to the previously cited, and holds that medical men recoder the same moral dity as their tizens in it uses where they become

an reof the mm son i nme t report it to the auth rities. The beauth rities are different opinions when b ought to the ttention of the British Medical Associatio caused t | ppoint a committee to confer with the Lo I Chief | tic pon this important question. This dip tit was received by the Lord Chief Justs on M 3 3 9 5 nd the sum mary of the esolutions passed by the Royal College f I hysicians f Lond nsequence of sald interview is as follows. That med cal practitioner is not justified in duclosing of rotation bislined i the course of professional tirida pon woman w tho t her coment but that when he is convinced that a criminal borns ha been performed on his patient be should g her especially when she is likely to do to mak to tement which may be taken as evide ce gainst the person who has performed the operation pro-ided also ys that her hances of recovery are not thereby prejudiced and that in the eve tof he refund t make statement be is under no legal bligation t tall for the a two that i the vent f the patient dyi g

he should refuse to give certificat of the cause of death and should commune to with the coroner JUR. 1 CULTALITYO.

GYNECOLOGY

UTERUS

Goodwin, R. T.: Lacerated Cetyly Med 016 11 511

The author reviews the anatomy of the cervix, gives the most frequent symptoms of lacerations of the cervix the results produced thereby and concludes by discussing the operative treatment

Lacerations of the cervix are very common. The chief cause of cervical tears is meddlesome obstetrics for example want of care or judgment in the use of forceps premature rupture of the bag of waters the injudicious use of the drugs ergot and pituitrin mechanical dilatation of the cervix and roughness in

performing podalic version.

The symptoms are not pathognomoni and are due to the lesions caused by the la eration The most constant of these secondary conditions are subinvolution of the uterus endometritis and uterine displacements and the symptoms usually described as being due to lacerations of the cervix are in reality caused by one or all of these complications. Backache bearing down in the pelvis vertical headache leucorrhora menorrhagia m tror rhagia sterility and abortion are the most frequent of these symptoms

The results of the la erations are either immediate or remote. Of the immediat results the most fre quently observed are hæmorrhage, sepsis and vesicovaginal fistula. The principal remote results are subinvolution of the uterus chronic endometritis. uterine displacements due to subinvolution or to contractions of cicatricial tissue in the cellular stru tures behind the uterus chronic tubal and

ovarian disease and cancer

As a large number of lacerations require no treat ment whatever it is important to have a clear and definite idea as to what class of cases require operative interference

The following rules have been formulated for this purpose

1 Operate upon all lacerations which are complicated with induration and hypertrophy of the cervical tissues eversion of the intracervical mucous membrane cystic degeneration and erosion

2 Operate upon all lacerations which are re sponsible for subinvolution of the uterus endometri

tis and uterine displacements

3 Operate upon all lacerations which are assocasted with a sensitive plug of scar tissue in the angle of the wound.

Any grave pelvic disease is a contra indication for operative interference in laceration of the cervix. There is always considerable dragging upon the uterus during an operation upon the cervix and these manipulations may cause a fatal peritonitis by breaking up old a thesions RALIE H KULS

Percy J F The Problem of Heat as a Method of Frentment in Inoperable I terine Carcinoma I w G IC You W h mion o o M

There are three stages to be recognized in the de elopment of cautery treatment of ar moma of th uterus (r) that in which it is used merely to stop hamorrhage and limit offensive discharge (2) in the galvanocautery excision t the cervix uters developed by the late Dr. John Byrne of Brooklyn. (In this technique a degree of heat utherent to cut the tissues was used: (3) in the dissemination of a coagulating degree of heat through the widest area possible of the an r mass with no attempt at immediate expansion of the parts (Percy)

The technique of Byrne was not designed for advanced monerable cancer in which the ut rover vical junction is fixed with extensive malignant and inflammators inhitration of both broad ligaments and the perimetrium. As classifind today. By me operated only in the first steps of cervical ancer involvement. He deplored the use of the cold teel knife in cervical cancer and forty-four year ago re ferred to it as a comparati ely fruitless procedure This is just as true today - without the preliminary use of heat - as it was in his fay cases treated by Byrne with galvanocautery exusion of the cervix were the type of sea which would be considered suitable for the Reis Wertheim treatment of today

The author has the following to say as to the future of the heat treatment The tage of operability with my present technique is easily so per ent and I confidently expect that if the promise which I see in my work is realized in the further development of the use of heat in canc r the stage of operability will be without limit in strictly pelvi cancer. I would not have you be heve ho vever that the ideal is mere operability Back of it all is the hope and promise of r sults never before obtained by any method so far de veloped in that disease which has always stood as a synonym for in urableness pelvi cancer In conclusion permit me to re-imphasize the following points

The Percy technique so- alled is not a cautery operation I remove nothing. The tissues following the application of moderately low degrees of heat are literally coagulated and slowly dissolve It usually takes two weeks for a healthy granulating surface to appear beneath the gradually dissolving mass of inert cancer debris.

"The operation of Byrne was a high galvanocautery incision of the cervix. There could be but little penetration of heat. Byrne recognized this when he advised that the surf ce left after the removal of the gross mass be seared over with the cautery knife in order to set all the heat penetration possible B t Byrne never th ught of polyi g heat t the degree of obtaining penetration sufficie t to render movable the fixed tissues in the pelvic basin. If the fixed time a malianant and aflam matory are not made freely movable as they renormally the heat penetratio has not been sufficient and, therefore is ineffective

To coagulate a large mass of uterine cance equires from thirty t sixty mi test nd f the broad ligaments still remain stiff fixed an ad

ditional ten minutes.

4. In my effort to emphasize the imports ce of avolding the burning temperat res, I fear that I have led many surgeons to the opposite extrem

d that they are trying t destroy the activity of an inonerable mass of cancer with temperature so low that days, rather than hours, would be required to make the heat effective. Byrme fried his timues. I broil or pesteurize them The Byrn technique was based on the use f heat as a neut process Mine is n t cute, but chronic, both as t time a d degree. Heat more beat and yet more bent but heat, not fire brolling not frying not reasting but curdling pasteurization, not desiccation congula tion, not ca bonization.

In its practical application, the whole technique can be summed up I the one statement. Do not carbonize the tissues. For in the degree that this is don in that degree is heat penetration inhibited and beat penetration is the vit liv essential thing A gentle simmering sound only should be heard when the ear is placed ear the vaginal water-cooled peculum. This simmering sound is produced by a ranges from 83 t 93 C (3 F) It probably ranges from 83 t 93 C (80 to 200 F) Heat in the cancer operable or inoperable or as preliminary to the use of the cold steel knife has, with it present development come t at y It offers more in the way f cure in the early case that a y other treatment so far devised. In the lat case it promises surcease from uffering ith prolongs. tion of llf that is most boneful

B t more than all else w have not yet fully learned the technique of most effectively destroying cancer in the accessibly regions of the body by beat When w d another chapter will have been written i the history of man contest with his physical ills that will compare very favorably with a vihing so far accomplished along the lines of scientific endervor

Gallant A E. The Removal of the Troubleson Unelcon Uterus. 4 1 H J o 6 cffi, 485

Eliminating hysterectomies for (1) life-destroy ing disease and (2) for conditions detrimental to bealth or dangerous to life, the author goes on to the consideration of (1) removed of the uterus be cause of conditions the source and cause of healthdestroying discomfort troublesome because they were the cause of intractable suffering useless because they were either absolutely relatively or practically incapable of performing the one sole function of th uterus-reproduction. In a women between 57 and 73 years, who had ceased to men struste the scalle uter were removed because of prolanged bladder with or without rectocele or descent of the uterus or intestines, in 7 cases uterosacral ligament retrofixation, 4 cases chronic pyrometria and ovarian sarcoma (?) one case The second group included I women whose ages ranged from 37 to 47 years, and who were still menstruating. Four had passed the approximat are for the menopause from a to 11 years while ther I still had in prospect from one to five years longer to flow normally. The average range of fertility was from one to seven children, the most recent birth seven months previous to operation the average length of sterflity was between six and SCYCE VERUS.

The third group included 7 suffering women between to and 14 years, in the full tide of rep oductive activity who had not been benefited by local and general treatment or by conservati e

operations. Gallant, when deciding to operate or not to operate was influenced largely, by () the severity the symptoms, (s) the effect on the general health and (3) the environment. Excessive ner vousness was the one predominating complaint in all but one instance Dysmenorrhess came next in rder of frequency usually of a severe type lasting throughout the flow and compelling the sufferer to lie down for a few hours or go to bed for one, two or even three days of each period. Back ache was a very common symptom, located by placing the hands over the sacral region, variously described as come and go pain dragging, tearing bearing down falling, and present all the time during the mouthlies, not so had between, etc. but to each one very trying and very real. Head ache, suboccipital was present in over half the cases, and of a truly torturing variety relieved only by some sort of dope. Illo-abdominal pain, when not of appendicular origin was of a dragging tearing burning character and referable

tension on the round by ments or enlargement or adhesions of the tubes and ovaries, distinguish abl from the appendix only by actual palpation. Dyspareunia was present whenever the vasina was raw r the terosacral ligament immobilized the uterns.

Dynaria with f equent pai ful urmation was nearly always associated with a demonstrable trigonitis, an acid vaginitis, and acid urine of high specific gravity

The conditions calling for operation were prolapsed bladde with or without prolapse of the uterus and rect m. r cases retroversion 7 cases 16 cases hypertrophied uterus, uterine tixatio 5 cases anteflexion 4 cases incernted cervix. 6 cases perineum, I cases diseased ovaries and t bes, 6 cases persistent vaginitis, 6 cases with goiter 3 cases viscerontosia

The operative measures employed were varinal hyst rectomy o times, with sulpingo-cophorec tomy i case complete e cision of vagina 3 cases partial excusion, a cases supravaginal a cases with

aries and t bea, case belominovaginal pain cases abdominal pain 2 cases anterior colpor haphy 2 times perineorrhaphy 6 times appen decectomy 4 times uterin drainage, Irainage through the cervical at mp times con servati e (?) mputation of cervix, a times resection of sigmord 1 case. This last patient died in the with day after peration, presumably from runture t the fit f the resectlin brought about by her t enuous if rts t work soiling the bed. One other hed 8 days after complete los re of the varing from hypost tic pneumonia.

In con lusion (allant states his belief that re troublesom useless uterus is not only just hable but the most rational procedure in the

toll wag nilitions

In sen! women, compilte depudation and losure of the vaginal canal is the one sure and parmanent me us of curing bernia vaging.

- I well nourashed women who have ceased 1 menstruat r who have passed or are approachg the approximate age when the menses abould cease hysterect my d partial colpectomy will prove beneficial and still provide for marital relations.
- 3 I menstruating women under thirty five years. Her every means to conserve childbearing function have been exhausted when the conditions cause lif of semi-invalidism when they prevent her from working and earning a livelihood when they seriously interfe e with her duties to her husband and children and condemn her to a lif of unalloyed suffering, then and then only as a last resort, abould the uterus be removed

 Whenever the pelvic conditions are associated with a troublesome, colicky appendix, or simple or exophthalmic golter they should be removed.

5. Whenever combined with visceroptosis a cure cannot be expected unless the patient is fitted with an appropriate corset.

ADMEANL AND PERCUIERINE CONDITIONS

Monchcowitz, E: The Relation of Anglogenesis to Ossification Based upon the Study of Five Cases of Calcification and Ossification of the Ovary Bul. Johns H pkins Ho p 916 xxvii 71

Within a comparatively short time the author has been able to study in the nathological laboratory of the Beth Israel Hospital three cases of calcification and two of ossification of the ovary The lesions were studied particularly from a morphological The process in each instance involved viewpoint a corpus albicans. The specimens represented an apparently continuous series in which four stages were recognizable (1) an early discrete multiple deposit within a healed corpus luteum (2) a defin itely circumscribed deposit of amorphous lime within a corpus albicans (3) the formation of primary haversian canals which is accomplished by the genesis of an active mesoblastic tissue both upon the surface and within the interior of such a circumscribed lime deposit (This mesoblastic tusine is derived from the adjacent blood vessels of the ovary and the predominant activity is the d vel pment of new blood vessels associated with this

14. 1

area filled inh delicat fibrous trans thombiast and you blood vessels. Along the circumfrence of these pare fibroblasts which have presented into the surrounding lime naming tissue reveal is a poid int. I me absorption. (Moschownt.)

activity 1 the devel pment of osteol last from the mesenchymal cells 1 (4) from bone 1 rmain with maturetion of all the elements described above together with eccentric deposition of bone plates around the primary haversan canals and the formation of marrow.

Moschowitz states that the davelopm at of new blood vessels affords the keynote to the interpretation, in terms of cellular ontogeny of the process of ossification and that the histological c nistrates which eater into the formation of a w blood vessels are the progenitors of all the histological components of esseous tissue. In other words, that blood vessels, ost oblasts bone cells and marrow (in part at least) are merely differentiations of the mesenchy mal cell unit.

To his mind the author's specimens furnish from corroboration of the adaptive or mescach in all theory of angiogenesis, and to the theory of the non-specificity of endothellum Ossincation he believes does not occur without preliminary calculation, and calculation occurs only in dead tustics, and there is no right reson for regarding bony structures within the orany a Hartomata.

O'Shansky A. L.: Infection of Ovarian Dermoid Cyst with Typhold Bacillus. J. 4 m M. in g 6 levi 888.

Two mooths after an attack of typhold fever a school-teacher aged in moticed a man in the abdomen. One month later are was operated upon. A large orarian cyst in the left islde was aspirated and bout two quart fithin pus removed. A few strands of hair were attached to the cann in an ermoval. The tumo was ligated at its pedicle on removal.

and removed.

On bacteri logic examination, smear showed a gram negative bacillus. The growth abo ed gram-egative motile bacillus in pure culture.

which did not produce gas in a gar mediums, d d not liqu fy gelatin and-did not coagulate milk Pathologic examination of the cyst i gros after fixation revenled a growth 5 by 5 by cm. in

its largest diameters. The falloplan tube was attached on one skile. When the cyst was opened quantity of graylah liquid, or 1 lning a faillike substance such as is commonly found i dermoid cysts, came out and masses of this fatty mat rial containing bairs were removed. At one portion, where the wall was thickest there was a tuft of hair growing from the wall. At another portion there was a short nipple like projection somes hat calcified. Microscopic examination revealed an infected ovarian cyst.

The patient made an uneventi l recovery and has had no further complications.

EDWARD L. CONTELL

Abelio, G. Strangulated Fallopian Tube Ovary nd Intestine in an Infant J. 4m. M. 4 o 6 lxri, 8 p.

The patient was girl aged a months, breast fed, and with no febrile or diarrhoral disturbances of any sort. Three months previous to operation he developed a mass in the right inguinal region, th appearance of which was associated with apparently severe bdominal pain and vomiting Prio t this no such mass had been noticed by the parent Taxis was successful in three attacks. To months later a mass preared in the right inguinal region the baby began to cry as if in severe pain omiting set in. Unsuccessful attempts at red ction had already been made. She had had no bowel move bout 48 hours. Examination revealed a somewhat distended abdomen, not by any means tense and right inguinal mass, about 5 cm in diameter and elevated above the mal skin level to the extent of about 2 cm. This mass was ex quisitely tender and very tense. Immediate oneration was advised d performed.

An oblique incision bove the mass displayed a well-formed spherical tense dark-colored peritoneal sac bulging directly forward through the extensiring. The contents consisted of a large almosed sized mass, readily recognized as the ovary to the postero-external aspect of which was att ched thry fallopian tube. Post rio to both was a knuckle tion on the litestin w m d a Kooher die et r inserted betwee 1 nd th nick of the size and the latt 1 kell enought nall reducto t be made if th hemisted was r Se eral mil use if the release 5 the constructing etk the overy had to reduced about too per cent use nd their testine as became a very deep red. EXTERNAL GENITALIA

Gelihorn, G and Ehrenfest, II Syphilis of the Internal Genital Organ in the Female T 4m Gymc Sec Washi gton 9 6 May

At present it is impossible to estimate even pprodunately the full extent to which yphilis exist to the world. The I test statistics which tend to show that per cent of the male population of the United States are affected are probably far too conservative.

Syphila ha als yas been assumed to be consider ably commoner among me than mong romen but from cert in in estigations this supposition cannot yet be accepted as conclusive. At any rate syphilit is common enough in women to constitute a gynecologic problem in the widest sense. Not every decase in a syphilitie to nature

but syphili it present will exert an influ nce of its own upon oexistent diseases. Moreover latent syphilis prevails more in women than in men

The course of syphilis in men differs in many points from that in women To cite i ut one of the differences the relative fremi nev of tabes and parens in the two sexes is well kn wn

Syphilis of the int mad genital in v men presents a number of problems as yet un-of red. The question of infection by the sperma of a syphilitie man is discussed also the postibility it differences in the strains of spirochetic which might have a predilection for one part or the other if the female cenital tract. There is finally the question whether certain part of the genitalia possess a sort of relative immunity

Primary change is of the vagina at rare probably because of pertain histologic and biologic character. istics of the vagina. The typi al sign of self onts of a mucous membrane Le par hment lik nduration persist as a rule only for a short time ordinary cir umstances spontaneous restitution occurs after about two wels. The absence of definit symptoms such as pain or vaginal list harge and the insignificance of any rinaining surprobably result in many cases in failure or even inability to orrectly diagnose this less n

Secon lary syphilitic lesions of the verna are ery rare. They occur either in the form of marules or papules the latter viriety seems to be relatively more frequent. They have no symptomatology of their own, and therefore are discovered only accidentally during an examination with the

speculum Tertiars luctic manifestations of the vagina are also extremely rare. They represent as a rule the continuation of secondary lesions in the vulva uterus or adjoining organs. The isolated submucous gumma breaks down early and appears in the form of a more or less characteristic ulcer. The more destructive processes which eventually lead to the formation of fistulæ and strictures almost always originate in structures surrounding the aging Tertiary lesions of the vaging do not exhibit characteristic symptoms such as pain or discharge

I rumary chancre of the cervix represents the best known and most common type of syphilitic affections of the female internal genitalia. Its frequency has probably been overestimated Statistics based on a large number of observations have never shown a frequency of over 1 5 per cent of all primary chancres found on the genitalia. It must however be admitted that in a considerable number of rases its presen e on the vaginal portion of the cervix is overlooked

Primary chancre of the cervix does not givrun to any noteworthy clinical symptoms. There fore as a rule a search first is made only after the appearance of the secondary evanthema. Under normal conditions the primary lesion heal with su h rapidity that its exist nee in a large percentage of

ases an all he urmised from rian findings which the modes are not burn term

Vieven luring its vist notice the primary han r ft ratruly characteriti in l rithognostic a pection a unit of it rapid and var gated evolution from an unerod I in lurat not an ul richich in turn either hals qui kly r transf rin, int an in a fiu us r si a

Unil time the absence of pulpall suillit bul as and the data of assertaining the har a tiri tic infuration of it base a uspi iou looking nth rix an builentia d sirm ri hird have always the prochets pulled, a be r red i mit uin and if the ervialles i

Syph.1 main. first itself upon the revix in th. firm of majulis. parules and ul crations. These forms probably represent three u cessay stages in the devel p m nt of a l-mon caused by watter d a rumulation of the spirocheta pallida in the squam u mu sa of the ervix. I'm parasit can realily be recover dir m the secretion fant fithe thre torms and this explain the great infection ness as ondary lesions. Wassermann is positive in this stage Vacules and papules have n vmptomatology of their own whill ulcers may give rise to a profuse vellowish discharge. Occasionally a necultar puffiness of the formices may be cresunt. The leucoplasti appearance of marules the acterists form of the papules and the typi al vellowish olor of the ulceration render to grown comparatively ea v Secondaries in other part of the body form a valuable and Cervical leaons as a rule heal quickly and may disappear without leaving any traces. Specific treatment energetically applied brings about resolution in a very short time

Actual knowledge concerning syphilitic lesions of the uterine body is extremely meager. Primary and secondary manifestations have not yet been observed in the uterus. A few instances of gumma in the uterine wall have been recorded. An isolated observation by Hoffmann proves the possibility of gummatous changes in the adometrium intrequency of tertury lesions is a matter of sur prise for the uterus more than any othe internal organ of the body is exposed to direct infection Spirochata may reach the uterine cavity from the vagina or lesions of the c rviv. It is certain that an a tively syphilitic mother invariably infects the fætus. In e ery pregnant yphilitic woman pirochetæ must be i resent in the endometrium. Un less syphiliti lesions of the uterus hav been over looked in the past we are forced to assume a relative immunity on the part of the uterus

It seem possible that the tubes may be the seat of luctic less us, but the pathological and clini al material on record is yet too incomplet to permit of positive a sert in Spirocharta ha e n v r

been found in the tubes of vibilit a women.

ment syphilitic cophoritis, tertiary scierosis of the overy overian gumma) have been described as typical expressions of the secondary and tertlary stages of fuetic infections, but in no instance with the possible exception of H fimann a case, has positive proof been furnished that such alterations are actually due to a local leutic process.

The fact that in some syphilitic patients either an amenorrhosa or more commonly a metrorrhagia, disappears after specific medication cannot be accepted as evidence of a syphilitic ovarian lesion Spirochetæ have as yet not been demonstrated in the ovaries of adults.

Syphilis of the privic cellular tissue appears in the form of a diffuse gummatous infiltration which secondarily involves the pelvic peritoneum. few cases on record the authors have added

personal observation. In almost all instances a wrong diagnosis of malignancy has been made. In their own case the positive outcome of the Wasser mann reaction together with other unmistakabi signs of tertiary syphilis about the outer genitals aided in arriving at the correct diagnosis. Specifitreatment produces amazingly quick improvement

of an apparently hopeless condition. Syphilis may be the canastive factor of dist rised menstrual function for various reasons. Impair ment of general health and disorder in the harmonlous synergism of all endocrane glands through the affection of one may in the course of a luctic in fection interfere with normal ovarian activity Therefore, in syphilitic patients specific medication may correct a menorrhagia or metrorrhagia which has proved refractory to the customary modes of treatment. Such prompt therapeutic effect, how ever does not permit of a diagnosis of luctic pro-

cesses in the uterus or in the ovaries, because uterine lesions probably never and syphilitic ovarian lesions, if actually existing, are but rarely responsible for abnormal uterine hamorrhages. The Wassermann reaction is found positive in a

very large percentage of patients suffering from metrorrhagias. This is not surprising. Luctic women through the common complication with gonorrhora and as the result of frequent abortions are particularly proce to develop gynecologic anom alles in which irregular uterine hemorrhages represent a predominant symptom.

The authors recommend a trial with specific therapy before radical treatment is decided upon for all cases in which a uterine hemorrhage is not defi-

nitely explained by local findings.

Normal cervical secretions may contain spirochate during the secondary stage even though there are no specific lesions about the genitalia. This has been definitely proved by the authors by actual observati n. The search for spirochetic may become as important a part of our diagnostic technique as is the stain for gonococci. The prognosis as to the danger from infection as well as the time of cure may depend upon such an examination.

As regards the uterus and more particularly the cervix convincing proof of the interrelations of syphilis and cancer are meager and it is necessary for the present at least, to rely the fly on the analogy with other regions of the body. The following four possibilities suggest themselves An literation of all tissues of the body caused

directly or indirectly by the syphilitic virus -Genethi mitimm g of Neisser-whereby the de fensive pparatus of the organ sin is weakened

2 Any part of the body which the past has syrhilitic lesion becomes a been the scat of locus m nor istentia wherein cancer may de velop Leucoolacia may represent the connecting

link between syphilis and c "7 4. The direct transition f yphilitic into car

cinomatous t wu Microscopic sections are troduced t illustrate the probabl mode of such transf rmation. Unless

arrested in tun by antifuenc treatment, atypical cell prollferation such a stim lated by the syphilitic lesion may lead t carcinoma While act I and well est blisbed f ets regarding syphilis of the female genital organs are ompara

tively few in number in ont all tract o t th many theories and the rolume of hterature on this subject yet enough is know to compell and hold the interest of the gynecologist Syphilis may cause organic lesions in all parts of

the genital tract such as ulcerations and tumefac tions. The gynecologist will be ble to properly interpret and treat uch lessons only if he is familiar with the local path logy of syphiles. He may also meet with f actional disturbances within the genital phere of explainable by any local findings, which may be due directly or indirectly t the in fluence of syphilis.

There are close analogies between the genital organs in the male and the female from a purely developmental and anatomical point fiview. The fact that the ovaries correspond to the testides, the t be to the epididymia, the uterus to the prostate has seemed to many writers sufficient t base deductions as to the pathology of syphilitic lesions in the female upon their knowledge of luctic lesions in the male. Such reasoning is faulty Syphilis in many respects affects woman in manner essentially different from man. After all, there is nothing in man to compare with disturbances of menstrual function which so often confront the gynecologist.

Gynecology has in the past profited by the pioneer work of dermatology in the realm f syphile. It is now time that the gynecologist should contribute his full share. There are still many mooted opestions, such as syphilis without primary lesson or the pathology of local lessons in the female genital tract which the gynecologist is amply fitted t solve.

He should also fall in line with the representatives of other specialties in advancing the problem of the relationship between cancer and previous syphilitic lesions in the same locality

Familianty with syphility less no in the central tract must needs prove of eminent pra ti al value to the gynecologist in view of the frequent infusion in the diagnosis of ancer and while all eration. or gummata. That or as mally a ration to sublected to a serious radical operations his been cured by antiluetic treatmen thir an bein doubt

PREGNANCY AND ITS COMPLICATIONS

Van Slyke, L. and Vinograd Vilichur A Quantita tive Test of the Abderhalden Reaction 1st JObst N Y 96 leads 90

Owing to the great uncertainty which has been associated with the Abderhalden reactio the thors have we ked in the hope of providing a quanti tative method sufficiently accurate simpl specific f proteolysis t make the results definit and free from subjecti influence. They con fined themselves t study of pregnant with mual serum. They utilized placenta prepared in three different ways

As standard method for measurement of serum protease the minonitrogen determinatio seemed to them particularly promising for the following reasons First it is quantitative and permits accurate results with a small amount f material. Second, it is specific f proteolysis. The change of the non-ammonitrogen of proteins into ami onitro gen is characteristic of protein digestiand the extent of this change affords a direct and quantit tive measur f the extent t which proteid digestion occura. The method since its publication in 910 has been used successfully in studies of protein direction by various investigat ra-

As nearly as possible the same amount of placental tissue was used in every case. Th tmost care was taken to avoid bacterial contamination, and the technique was controlled by means of repeated cultures with negative result. The chemical manipulations were simple clear-cut, and quant ta tive. Duplicat controls always gave closely

agreeing results. Practically every serum, whether from a pregnant or no -pregnant individual showed some definitely measurable degree of digestion when incubated with placental tissue. The range of individual variation in proteolyti ctivity was wide. The result with normal sera cover in each case range which incl des most of the result from pregnant sers. After year' work using the utmost care, the uthors found that the individual variations of both pregnant and non-pregnant sers make the results from both overlap so compl t ly as to rende the tilization of the reaction even with a quantitative technique

Bell R. G. Creatrean Section in a Pitman a Cottage B i M J. 0 6 1 105

The author reports a casarcan section performed under unusual difficulties in a case of contracted pelvis. The two previous labors had ended in the sacrince of the children. Operation was successful in this instance a living ehid was delivired and the patient had a smooth convolescent puerperium Exception might be taken to the opinion expressed by the author that many major abdominal operations could be done quite as well at the patient is home as in the hospital Certainly with the history of the case in hand transportation to the hospital could have been effected long before the time of the operation the need for which was evident.

Tweedy E. H. The Lower Uterine Segment Its Origin and Boundaries. Lan 1 Load of ct 505

It requires only a very minute portion of the upper portion of the cervix to suffice for the growth of the lower uterine segment. We must think of the cervix as growing large rapidly rather than of its being rapidly stretched. These changes in the growth of the cervix result from stimulation by direct pressure exercised by the ovum during the latter half of programs, and during labor. To understand the progress of the growth of the loweuterine segment it is important to keep in min-1 certain establish d-anatomical and phys-ological features. The endoperitoneal tissue f-rms an important disphragm for the pelvis. His thers are inserted into the muscle bundles of the uteru and may be const fred the Indinou threnthes of the latter The disphragm is held in tension by the uterine muscle it supports the uterus, prevents descent of the contents of the abdomen and constitutes a barrier which effectively protects the cer vix from pressure. The os internum opens at an early period of pregnancy and this relaxation corre sponds with Hegar's early sign of pregnancy Consequent on this opening the uterus and abdominal contents sag downward and the fornices become somewhat shallow. The uterine musclefibers are put out of tension by the opening of the ouwith consequent contraction and retraction of these fibers and the upward movement of the diaphragm with its ttached blood-vessels and ureter This upward movement produces a still wider opening of the diaphragm, permitting the growing ovum to pass through it and allowing the latter to exercise direct pressure on the structures immediately beneath. Bearing these facts in mind we must conclude that the cervix is not an elastic structure, but, on the other hand, that it has a power of extraordinarily rapid growth when stimulated by continuous pressure. The similarity in the growth of the cervix to that of the growth of the lower uterine segment is very apparent, and we have no difficulty in following its subsequent development into the part known as the lower uterine segment. The ring of Mueller must be considered the undilated portion of the cervix which has as yet not been sub-jected to direct pressure and Bandls retraction ring must consist of the structures which so to form C. D. HAUCH. the internal or.

Irring F C. The Systelic Blood Pressure in Pregnancy; Observations on Five Thousand Consecutive Coses in the Pregnancy Clinic of the Boston Lying In Hospital. J 4ss. M Am 10 6 hrd, 535.

In 80 per cent of pregnant women, the bloodpressure ranges from 100 to 130

In 9 per cent, the blood-pressure may be below 100 one or more times. A blood-pressure below 90 does not mean that the patient will have shock unaccompanied by hemorrhage at confinement. In 11 per cent of cases, the blood-pressure may be

above 'yo one or more times. Age nationality and parity seem to have some influence on blood pressure. High blood-pressure in the young is more irequently a sign of toucomia than in those over yo. Elevated blood-pressure is more commonly an index of toucomia than is albuminumia, and it is ant to be an earlier sizn. The dorree of elevation

apt to be an earlier sign. The degree of elevation points more surely to the likelihood of toxemia than does the degree of albuminums. Both, how

ever are of the utmost importance.

Isolated cases of elevated blood-pressure unaccompanied by albuminuria or evidences of toxicals occurred not infrequently. Usually they responded to free cathasia's Some pressures remained elevated of in spite of treatment and apparently were nor mail, during pregnancy t least for the patients who cathibited them. A progressively rising blood-pressure, often from a low level, even though it nover reaches the arbitrary danger point, should be regarded with apprehensias most valuable sign of approaching totamus. Toxemia is much more common with a blood-pressure above 50 than it is below that point

Most cases of eclampsia occurred with pressure of 60 0 more Eclampsia may howeve occur

with a moderately elevated blood-pressure All toxemics developed both albuminuria and

elevated blood-pressure.

While the incidence of eclampua in this series is about the same as the figures usually given, it is significa t that two thirds f the patients who developed convul one absol tely neglected advice and refused t return to th clinic. Had these pa tients been discharged against advice during preg nancy for disobeying instructi us, very favorable statistics would have been obt med. The hospital feels that it would have been most unjust to the ignorant foreigners, who constit t the vast major ity of is patients t desert them when they most needed skilled hospital care With proper co-operation from the patients and eliminating the fulminat ing cases which develop in a few hours, there is no doubt that eclampsia would be practically pre EDVARD L (YELL ventable disease

LABOR AND ITS COMPLICATIONS

Wichmann, S. E. Th. High Forcers Operation (Zur Klinik der bahen Zangrooperation) Avril and Ark. Stockholm, 9 6 Kurryi N. p. and No. s. p. 3

The author in a very detailed and comprehensive article deals with the clinical data obtained in soo high forceps operations in the obsertrical clinks of the University of Helsingtons from the beginning of the year 800 to the middle of 9.4. A short nummary of each case is given. The matter is so diffuse and actessive that only an outlin f the points discussed

by the author can be presented in an abstract Under the heading of material Wichmann dicusses Choice of the cases distribution of the material according to differences of material pelves, size of the children the manner of presentation of bead in pelvis indications calling for high forceps operation age of the mothers and number of labors. Under prognosis of high forceps operation, the

following points are considered

r For the mother (1) mortality () injuries,
(3) post partem hæmorrhages, (4) morbidity (5)
late results.

3 For the child () mortality () as regards the pelvis and weight of child, (6) age of mother and number of previous births, (c) indication to open tion, (d) mobility or fixation of head () causes of death of the children (3) injuries, late results.

The technique of the high forceps operation by various operators is discussed. Finally the value of the high forceps operation as regards position of the operation in the therapy of the contracted pelvis and significance of the resistance of soft parts as regards prognosis for mothers and children in high forceps operations. The article is accompanied by an extensive bibliography U 1 BRENNAM

Mundell J J Pituitrin in Labor N 1 o 6 laxili tor

The author has reviewed the rather extensive literature which has accumulated on this subject during the six years this extract has been used in obstetrics. He has collected reports of 3 952 cases in which it has been used and gives a table showing the unfavorable results which have been reported by various writers. There were t d aths due to rupture of the uterus, but in each case the records show that these fatal cases were due to the misuse of pituitrin. He finds a futal mortality of 21 in 5 052 cases and a maternal mortality of

This study shows the need i careful analysis of all the factors in the case before reporting the good or bad effects of such a poverful extract as pituitrin.

Skeel A J Analdesia and Anaesthesia in Obstet ric Practice J 4m If 1 TO (la 1 o

In labors not distinctly abnormal morphine is used during the first stag and only then the labor is expected to last at least four hours longer The author's indications for morphine during the first stage are

A rigid hypersensitive os

2 Evidence of con iderable pain with a probable first stage of several hours, as in most primiparæ

The presence of nagging but meffectual pains which irritate and exhaust the patient out of proportion to results

A cordingly many patients particularly primipare get a single hypodermic of one sixth grain of morphine

At the beginning of the second stage or if the patient suffers severely shortly before dilutation is completed the use of gas is begun Intermittent administration is made at first that is during the pain only and with small amounts as 30 gallons of nitrous oxide to 15 gallons of oxygen head approaches the pelvic floor and finally strikes the perineum the nitrous oxide is gradually in creased in volume to 50 or 60 gallons and the inter vals between administrations are shortened. This gradual increase of the volume of the gas given is controlled by the patient a statement of pain or comfort during uterine contraction. As the perine um begins distending and the most painful stage of labor arrives the gas is given still more continu ously until, at the time of crowning from 70 to 80 gallons of nitrous oxide are given practically con-tinuously When the head is born the nitrous oxide is at once discontinued and the patient sharply revived by a few inhalations of pure oxygen.

If the woman is a primiparae with a rigid inelastic perineum and lacerations seem inevitable the utmost possible relaxation is secured by switching to other and pushing to complete unconsciousness at the moment the head crowns the permeum

The author enters a vicorous protest against the advice at present being so freely given that anyone may use gas in labor cases with perfect safety. is a powerful therapeutic agent with infinite possibilities for harm at the hands of inc moetent or careless users. The statement has been mad that gas in the hands of an expert is a safe angesthetic but the most dangerous anaesthetic if given ly a This is far too strong a statement to make concerning analgesia. Even here however some knowledge and experience are necessary to secur both safety and satisfaction from its use. Moreover the temptation to follow a gas analysis labor with a gas angesthesia for repair is so obvious that all those who expect to adopt this method should pend sufficient time in special study of the agents they are to use so that they can direct its administration This does not mean that a doctor must equip him self as a gas expert The skill necessary for its use in labor can be acquired in a short time but free use of gas by the absolutely inexperienced will surely lead to tragedies LDWARD I CORNELI

Francis, L. M. Treatment of Ophthalmia Neona torum B fale M J 10 6 km 144

The author not only discusses the treatment of ophthalma neonatorum but also those features in its management which are of interest to the general practitioner. The article may be summed up as follows

r Not all ophthalmias of the newborn are gonorrhoad to per cent are due to other organi ms as the staphylocoucus streptococcus etc

2 There are two classes of onhthalmas those primary infections occurring at the time of birth and those where the infection occurs secondarily from extravaginal sources

3 Early diagnosis is imperative. All new cases of ophthalmia must be regarded with suspicion until proven to be of a benign nature smears should be made early

4 In unilateral infection the other eye should be protected and the attendants warned of the danger 5 Because of the frequent serious corneal involve.

ment gonorrheeal ophthalmia should be under the care of the ophthalmologist 6 Careful and intelligent nursing is as important

C D HOLITES as medical advice in these cases

Barnert C.: Treatment of Gonorrhoral Ophthal Med Rec 10 6 lavely, 230.

The author has used creatin in a number of cases of gonorrheal ophthalmia and finds it an excellent drug. Cresatin is a phenol derivative of very powerful germicidal properties, entirely free from the corrosive destructive action of the or dinary phenols

The duration of gonorrhoad ophthalmia under

per

this method of treatment is twenty four t forty eight hours after the first applicatio. In most cases one polication was found sufficie t in one were more than two such treatments given. Gonococci were rarely found after the first pplicati where they did so appear a second pplication

effectively disposed f them The technique is as follows: A \$5 per cent soltion of cresatin in albolin is used. The conjuctival sac must first be cleared of secretion by means f stream of warm physi logical saline or saturated boric acid solution preferably through an undine. This is followed by the instillation of a drop or two of a one per cent solution of h locaine or cocaine to prevent the slight irritation if the n t step. A small cotton swab i used t pply drop of cresa. tin to the mucosa of the conjunctival sac. It is imperative t cover the entire surf re of the m cous membrane in this polication. The after-treat ment consist in Leeping the co junctival and free from pus and the repetition of the application should occasi demand. RALPIT H K TINA

Hannah, C. R. I J ries t the Infant Prod ced t Birth. T. St J Med. 9 6 xi 539

The author discusses the various causes for birth i juries, and gives the histories of four cases of long and difficult labor followed by injuries to the ini nts.

It is in cases of contracted pelvis that the infants suffer most. Here the use of the forcers produces a depressed fracture c cussion of the braior an intracranial hemorrhage ny one of which may cause permanent pathological change which in later hi may explai paralysis bealache epilepsy and other xisting maladies. Usually these injuries are the result of the nacientific pplication of the mechanics of delivery brute force is substit ted for proper and thoughtf I manipula tions. Prolonged nd hard labor pains, which pre ent a change in the fortal blood, are freque tly f and in cases f generally contracted polyis, and in cases with rigid and unyielding perincum

In conclusion the thor emphasizes the following points

That eglect of freque t observance of the fortal heart-sounds cost the life of many child. That a slow irregular feetal heart beat or ecesively fast one signifies fortal danger

That the presence of I mpy or sea-gree meconlum in the liquor in ii in cephalic present ti n may mean compression and fallure to recognize this fact hazards the life of the fortus.

That plt itrin may cause tetanic contractions of the uterus, and if so an interch age in the placental blood may be preve ted which would

produce hyperca bonization That an irregula and slow fortal beart or an

excessively fast one or the presence of meconium in the liquor mail are symptoms which indicate that the focus must be d livered or it will probably dъе

That if an attempt t d I ver is made it should first be made certain that the hill can be delivered alive I that t will probably live and second that the mother will of being red

That an I ternal harmat mausing i ternal pressure should be remo ed early or pathological destruction of the nervous ystem will tal place which may use deform uses imbecility epilepsy d other forms of degenera v Rules H. Kurn

GENITO-URINARY SURGERY

ADRENAL, KIDNEY AND URETER

Thomas, G J Clinical Review of 249 Coses of Non-surgical Infection of the Kidneys and Ureters. Ursl. & C tas Res. 9 6 xx, 1 7 The author analyses 240 cases of renal infection

which received urological treatment in the Mayo Clinic. Tuberculosis and injection secondary to calculus or urinary obstructions are excluded. Frequency of urination is the earliest and most frequent symptom, 76 per cent. Cystitis, however, was noted in only 6 per cent of the cases. Renal pain was the initial symptom in 37 per cent and hemsturia in only 7 per cent although present at some time in 4 per cent. Ninety-five cases had bacteriologic examination and 63 per cent of these were colon infections. Thomas argues that the original offending organisms probably lessen the resistance of the kidney so that the colon bacillus which is constantly passing through the kidney be-comes pathogenic. The majority of infections are bilateral and should be considered so until proven otherwise by pyclography and cultural exmination. Contamination is frequent usually from poorly sterilized ureteral catheters or the use of an unsterfle

Inbricant.

such as toneth, teeth, abscesses, furunculosis bone infertious, etc. should be made before prolone. treatment is instituted. Of local treatment lavage of the kidney pelvis and ureters every four or five days was most frequently used lavage with o 5 to 3 per cent silver nitrate. Of 150 cases which were followed in 30 per cent the condition remained stationary improved in 46 per cent, and cured in 18 per cent. Of the 28 cases cured, 6 had autogenous vaccine only 6 vaccine and urinary antisentics only 4 urinary antiseptics only a pelvic lavage and a vaccines and lavage whereas, a cases had Three urinary antiscptics, vaccines, and lavage cases received no treatment, were operated upon and one had bladder lavage only FRANK HIGHAR A Method of Demonstration

In treatment a careful search for foci of infection,

Crabtree, E. G. A Method of Demonstrating Bocteria in Urine by Means of the Contribuya; the Relativ Value of Examinations by Culture or Stained Sediment. Surg. Grace. d. Obs., 916 XXII. 1

The author calls attention to certain unavoidable errors in the diagnosts of urbary infection where the clinician relies entirely upon cultural evidence. These errors are due to four factors

t The tendency of some common bacteria like the colon bacillus when recurring in mixed infections to overgrow other perhaps more significant bacteria. This occurrence is most troublesome infections with phosphatic calcult and fections of the kidney where a colon p already exists 2. The tendency of chromogenic bar

scure ther more algorificant growths in ture.
3. The possibility of formalin te

small quantities of urine being washed of formalia sterilised cathet r sufficient to inhibit growth in culture

4. Routine culture f its t demonstrate more rare bacterial infections becausitable cultural conditions and media.

The calls attention t the value of stains as a control to cultural raminations.

urings as a means of viding the a By his method of eliminating pass from fuged sediment large numbers of hacter tuberce bacilli when present are de Safficient evidence as t the nature of organisms is obtained by stuned ow parallois to indicate p over cult ral Contaminations are really recognized infections by the number of Sacteria

renal infection.

Owing to the close relation of the intended to the kidney by lymphatic circulation fections of the kidney are easily accounte generally occur on the basis of intestina

and stais. In the etiology of urine stasis congenital renal anomalies of formation or location (horseshoe kidney dystoplas with anomalous vessels favoring stone formation, polycystic kidney etc.) play an important role. Schmidt has observed that many of these conditions are the nucleus f r later occurring renal infections. In it cases of congenital polycystic kidney, which came to operation, o were complicated with infections. The same is true of hydronephrons in the vast majority of which infection sooner or later necessitates operative interference.

Operative injuries of the ureter obstructive conditions connected with advanced renal neoplasms parasitic growths of the kidney and concrements of the upper unnary tract are cited as other and frequent sources for renal stasss and consecutive renal infection. In looking over his operative records the author found that unne stasss in the pelvis of the kidney was an important factor in miections of the kidney was an important factor in miections of the kidney was an important factor in the cases the colon bacillus could be demonstrated as the infecting agent and that but a small per centage of cases are ascending in character

Owing to the fact that obstructs e conditions of the urethra are more prevalent in males consecutive infectious changes of the upper urnary tract are less frequent in women than in men a f t that is borne out by the author's statistical compilation of

his own material.

The reverse is true of unine stasis due to pathological conditions in the bony pelvis causing pressure on the ureters, which are by far me common in the female sex. The greater frequency of renal infections in the male as evidenced by the authors statistics on his own work is explained in the basis of the preponderance of more favorable conditions for general infections in that sex.

The author concludes his ery instructure article by Insisting upon early operative relief for the great majority of cases of renal infection as a sequel to urine stasis. I wore expectant refirm may vield good results in the frequent cases of olion infection consecutive to congestion while in renal infections due to the more common pus producing rganisms only a tive surgical measures are fraught with satisfactory results.

Rumsohoff J: Unflateral Hiermaturia Surg Gynec. & Oist., 9 6 xxil, 75.

Ransohoff presents a case of pancreatic cytu, with what he believes to be the unique symptom of hamaturia. The tumor was in the left upper quadrant projecting int the loin, distinctly flux tusting and of slow growth. When first seen it was nearly as large as an adult head. Cytoscopic examination showed a bloody stream of urbox insuling from the left untertail office. Indipocaranae mjec tion demonstrated equal function on the part of the two kildness.

Ureteral extheterization and radiographing of the renal pelvis was refrained from an account of the weakened condition of the patient t th tim of examination. The barium injection of the rectum

showed the colon normal.

Exploration of th left kidney by lumbar medicion revealed a nonewhal larger kidney than normal. A diagnosis was made of cystic acromats of the lekthery. Lumbar exposure of the kidney showed it to be normal. Median incision them displayed the cyst of the pencreas, projecting between the color and the stomach, with the spleen six o capit times its normal size. The pressure of the pancreatic cyst on the renal and splenic ven had produced the hematuria and the enlargement of the spleen. The hematuria disappeared after the operati in.

So far as the author knows, the case is unique, since a search of the relevant literature has failed

to show another case.

The pancreatic matter of the cysis was demon strated by the presence of the three pancreatic ferments alkaline proteinose amylose, and lipose There were also present little masses of seponified fat.

Macedo, C. Th. Periods of Amelioration in Renal Tuberculosis (Los periodos de mejora en la tuberculosis renal) Crés. méd Lima 9 6, xxill, 13

From clinical histories the author deducts that during the long periods of arrest or apparent cure of renal tuberculosis, some symptoms improve and even disappear while others persist, revealing the existence of the primitive pathologic stat of the

kidney

The symptoms diminishing in intensity or disappearing are () lumbar pain () frequency of micrurition and (3) hermaturia.

The chnical signs which persist are () polyuria (a) albuminuria (3) pyuria and (4) bacillus tuber culosia.

Cyticocopic examinations have proved to the cyticocopic canninations have proved to the cytifis of a t bercular origin may develop into a chronic state, with a normal functioning of the urinary bladder () icetarices of advanced tubercular lesions may be observed (s) in such conditions characteristic cyticocopic aspects are met with.

Renal tuberculosis starts insidiously and develops without being discovered by the patient or the attending physician, then it confines itself to lesions of the renal parenchyma, latent tuberculosis.

When the petient has reached the stage of acute tuberculosis, producing aymptoms alarming to the patient and permitting of a diagnosis, the tuberculosis is sufficiently advanced to force the abandoning of all hope for a spontaneous cure or medical treatment the end-result is the destruction of the kidney. Although renal tuberculosis and sing if sing are incompatible the only abstraction then are more than the stage of the stage of

Simmonds, M. Danger of Pyelography (Ueber elne Gefahr der Pyelographie) Huenchen med. W huscht 9 6 mil, 29.

In case in which Simmonds made a pyelographic investigation to doubtful kidney symptoms, the patient died on the third day following. In this case cm of 5 per ce t liargol solution were fjected t th right kidney pelvi He revi wa some other reported cases of d ath following collarols of tion interctions.

From the utopsy made in his was asset is clear t S mmonds that collargol personing w not the ca we of death but that death resulted from a streptococcus septic in asson. There were apparent by romans in the rete by which the treptococci had found a mode f trance int the blood stream. While tuent clear what part the jection may have played the passage of the microbea, yet a s per cent sol til n was evidently not bactericidal. Among the dangers of pyelography therefore must be reckoned on that is usually ignored, i.e. septic infection. The surgeo must take special precautions to avoid injuries to the kidney tissues by the infusion, and if the bladder lower urinary passages are found to contain infective microbes it

is better to abstain from pyelography
W. A. BRENNAN

Grossi, V Glinkul Considerations of Amburd' Constant (Applications clinkbe della constant dl Amburd) Pelid Roma 9 6 xviii, sec-

di Ambard) Felici Roma 9 6 xvili, seckir 4

Groun has made an extensive study of the cinical small obtained by himself and others in the amplica

result obtained by himself and others in the application of Ambard constant. His own experience is based on 31 complete difficult cases in which the constant was observed 77 times. He concludes that Ambard ureaccretory constant is like various other methods of value in examining the renal function, indicating the gholed alteration of the functiof the kidney and that it can in its extreme limit. confirm a lethal prognosis or cause more caution in

making an operatory intervention. It is supto the calorimetric method in cases where cutheteri sation if the ureters is impossible

In regard to the numerical limitations imposed to

Chevassu, Gross believes that they have no absolute value and that the interpretation of the constant ought be made in each individual case according to the clinical criteria and the various causative factors azotemia, urec concentration, daily urice clumination.

In 5 patients dying from renal insufficiency the asotenials was always higher than 1 gram in one case it reached 5.2 gr per 1.000 in one case for some few days before death it fell to 0.3 gr. Three cases in which the asotenial was above 1 gr were operated upon successfully and recovered 1 died four months later.

The area concentration in cases of death was always below to per 1 oo. The daily elimination was still less and was associated with oligina. In 2 patients dying from hemotogenous infection of the kidney the constant and its factors were almost

From the surgical point of view great value should be attached to the ureic concentration and to the daily elimination which correspond in reality to Albaran's two-hour examination of the global urine and to Cathelin's analogous proce fures

The significance and pathogenesis of the azotemia and of the constant are very far from 1 ung clear. In their present state forcosi thinks that we must consider them as simply signs to which it is ne sary to attach great unportance perhaps just as much as to the albumin contents of the urin.

Wechselmann: Intravenous Injections of Lactose
Without Reaction: Sciayer & Kidney Test
(Ueber reaktionsise erlaufend tra cose
Michencherinfectionen) Berl M II kas kr
otó Mik, 84

Wechselmann has been using the lactose test for some years past and in many thousands of cases. His experience is that it is very reliable when the lactose is pure and furnishes a dependable index of the kidney functioning. The fill effects which some have found after the use of lactose are explainable as due to the presence of impurities

II A BREW L

Wyman M. H.: The Phenolsulphonephthalein Estimation of Renal Function in a Thousand Cases. J So C. M. 41 9 6 to 84.

The majority of the 1,000 tests were done on surgical patients at the Columbia (S C) Hospital

as a part of the routine examination

An output of o per cent or over comes only

from normal kidneys.

A 60 per cent output may be temporarily observed in cases where there are at the same time evidences of kidney disease albumn or casts but if the latter do not clear up quickly the output soon begins to decrease

When a sound Lidney is compensating unusually well for its diseased fellow we may find a 60 per cent excretion together with albumin and pusBut in 15 per cent of cases evidence of kidney disease is accompanied by an excretion below 60 percent

From the prognostic viewpoint the important thing is whether the curve rises or fill. A man may be regarded as a good surgical n k with an output of but 20 per cent previded the urve has risen and is stationary.

Hunner G. L. Ureteral Stricture Excluding Cases Due to Tuberculosis and Calculus Report of Flity Cases I im I of 1 St Louis 9 (April

In discussing stricture of the ureter the author is dealing only with the narrowing of the ureteral lumen due to intinuic disease of the ureter

The report of cases is further limited by excluding strictures due to tubercul us disease and those strictures immediately surrounding a stone

Thus limited inflammat ry stri ture is a far more common disease than i merly belie ed the author sides on the total property of the strips of the control of the total property of the strips of the

The author recognizes congenital narr wing as an it logical fact r in the disease but think its im patience has been greatly overe-timated and does not lassely any of his cases as due to this cause.

Other rauses are gonorrhoeal infection probably travelin up the lymphatics from the blaider and ryelinephritic infections with highers have considered as infecting the ureter by way of the urine stream. The author thinks it more probable that the ureteral wall involvement is synchronous with the pyelonephritic infect in and like it has a blood or lymph stream right.

Ureteral stricture from the ordinary pyogenic cyatitic infections is extremely rare. Traumatic cases follow operations childbearing and other sources of mury to the ureteral wall.

The author thinks that by far the greatest source of ureteral stricture is some distant focus of disease such as infected tonsils sinuses teeth or disease of the mattro-intestinal tract

In such cases the disease settles in the urcteral walls and causes the narrowing which in many cases is followed by dilutation and later by infection of the unpary tract

The symptoms of ureteral structure ar for the most part due to the obstruction and are identical with the symptoms of stone in the ureter. Some patients complain only of a more or les constant dull aching pain in the lumbar region. Others have this constant dull pain with acute exacerbations of pain in the kindry region and the pain is often reflected down the ureter. There may be bladder and rectal tenesmus. Such attacks may require morphia, and either the pain o the morphia may bring about severe n usea and monitor.

If infection be present the above symptom are likely to be more severe and are accompanied by chills high t moerat re and profound prostrat on The congestions incident to exposure getting the feet wet 'entching cold, and those due to the mensional period are likely to cause partial or complete temporary closure f the inflammatory area of t thus bring about a severe attack of renal pain. Spontaneous local pain at the stricture site is compating of in some cases

and it companies on its some case. The disposals is made on the history the urine examination, and the physical findings. As above stated the history is that of toose in the urster or of prelitis. The turner may be quite begat to be a superior of the control of

The observation that the urine may be quite negative in these cases is a most important one from the diagnostic standpol t. Too often with a negative \(\) ray and with bornal urine it is concluded that the urinary tract is of involved and renal catheterization and the obtaining of a pyelo-ureterogram are neglected. The patient is operated upon for appendictis, o some form of exploratory laps rotony is doe and the victim continues to suffer or to find partial rehef in expectant methods of treatment.

If the stricture be located in or hea the bladder wall, it may be palpated as a d finite thi kening indistinguishable from the i filtration usually surrounding a stone, and cystoscopy in uch case often abows reduces and ordens about the ureteral orifice.

If with the above history durinary a diphysic I findings one is unable by ray and a wax-tipped catheter to locate stone in the ureter probable diagnosis f stricture is funding.

Repeated obstruction to the renal cathet r at a certain distance from the bladder is further evidence of stricture.

By melting pure beswax od making a war spindle of the renal catheter t short distinct back of its tip one can appreciat the obstruction to this spindle a it meet the strotture and a more certain diagnostic feat ret in the long of this spindle on the stricture area as the catheter is withdrawn.

drawn. Additional corroborative evidence of tricture is the presence of hydronephrous although a mea surable increase in kidney and eter content may be absent even after years of recurrent renal tacks.

The trauma of catheterization is often followed by a severe renal attack and in the infected cases by a typical prelifit attack. In suspected ureteral stone or atteiure a large catheter or preferably a large catheter with wax bulb dilator should be passed to dilat sufficiently to avoid this adematous closure

f the lumen after examination.

The author has seen several cases in which the fluid conte t of the kidney pelvis was less than

norm 1. These are usually eases with a proton infect in which has resulted in contraction of kild y pelvis in spate of the mechanical obstruct lower down causing symptoms. A pyelo-uret gram in such cases shows the site of the uret stricture and a slightly dillated ureter above toolist.

The uthor takes definite issue with the prevail opinion that dilatation of the kidney pelvis reter are due to infection. Many of his cr with sterile urine nd no bistory of previous infect

have the dilated ureter and pelvis.

Of 44 cases with urine report 16 were sterile of these 6 have notes on the kidney conten of these were approximately normal, measuring spectively 8 and 12 ccm 7 had a hydroneph ranging from 15 to 30 ccm. and one exceptic case with clear urin measured 355 ccm.

Of 18 infected cases, 5 were measured 4 beins normal or less than normal size and the pelvi-11 cases veraging 130 ccm. In this series of c. the a erage duration of symptoms in the six cases was two and a balf years, and in the infer

cases four years.

The ideal treatment for stricture of the ureter i dilatation from the vesical approach. Dilata results in relieving the patient's symptoms and shrinkage of the distended pelvi and ureter infection be present dilatation is supplemented enal lavage although it is probabl that m cases would clear p without the lavage simply giving the urine free drainage. In the infer ases of long duration with immense saccula kid eys one may be unable to clear up the infect but after dilatation of the stricture the kid pelvi shrinks markedly the urine becomes m more clear and in some cases entirely clear exfor the bacteria and microscopic pus, and the t ent is restored to pproximately normal bea These facts are of "ital importance to those path with bilateral stricture. In the cases with me lateral stricture and with immense by dronenhroti pyonephrotic kidney conservatism often calls the extirnation of the kidney. This was done aix f the author a craca.

In cases that cannot be dilated by the ver approach the uthor advise extraperitoseal post of the ureter and retrograde dilatar. This was done on 8 of his 50 cases, with excell results in 6. Two of his early cases failed t obt complete relief probably because of insuffice dilatation.

Billateral stricture was demonstrated in 12 of ocases. It is probable that systemate examination would have above a larger percentage of his original to a some of these 12 had symptime on side only and the other side was accidentally be to have stricture in the course of a facilitiest or after relief of symptoms on one pide on the stricture in the course of the original test of the stricture in the count of the original test with symptoms in the patient returned later with symptoms in the lidines and these were found due to stricture the corresponding ureter

BLADDER, URETHRA AND PENIS

Woodall G W Some Problems in the \ Ray Diagnosis of Urinary Calculi 1/h γ 1/1 i

According to Woodall the Vray is but on of three indispensable means of diagnosis in tases of suspected urinary calcult. The other two are (t) a careful history and physical examination (2) a cycloscopic exploration and study of the unnary findings from the bladder and kidney.

He groups the cases from a roentgenologic vi v

point into three classes

I The \ray findings may be positive and easily confirmed by cystoscopic and other lata

2 The V ray findings may be negative and very misteading unless subordinated to other available positive data. Negative cases may suidenly be come positive due probably to some change in the composition of the calculi

3 Apparently positive \ ray indings may prov to be erroneous when checked by ystosc p and other means of diagnosis

Several case histories are given to illustrate ea h

group

Woodall considers the X my to be the most valuable single factor in the diagnosi of unitary valuable single factor in the diagnosi of unitary calculi and to be of indispensall servi when used in conjunction with a carefully taken histry and exhaustive study of the clinical papers. It is used alone however without proper confirmation by such meatus as mentioned it may lead to smou error almost as often as it would furm his correct diagnosis.

David K B Williams of the most correct diagnosis.

Kelly II A., and Nell W: Cauterization and Fulguration of Bladder Tumors J in M 1 19 6 1 72

The author reports two cases in which cauteriza tion and fulguration were done for bladder tumors

The first case a female aged 41 hal been twice operated upon for papilloma of the bladder live and four years previous, respectively. Two years previous cystoscopy had revealed an ulceration 30 mm in diameter on the posterior wall. There was a similar area on the vertex 18 mm in diameter Repeated lugurations covering a period of eighteen months cleared up numerous tumor masses. At present the ludder is normal except for two small recurrent areas about 4 and 2 mm in diameter about the right ureternal orlice.

In the second case a female aged 38 the cystose copy revealed a large papilloma attached to and filling the anterior surface of the bladder Cystot only aboved a growth 15 cm in diameter attached to the posterior wall and three large cautiflower growths on the anterior wall protruding into the urethra and including the left ureteral orince Nine tumors in all were removed. There was a recurrence two years later the size of a cherry near the left ureteral orince that the treatment of the control of

MacKenzle, D. W.: Double Urethra with Operation; Review of Literature. Surg. Gymrc. & Obr. o. 6, xvil., 344.

The case reported from the genito-urinary service of the Bellevine Hospital was that f a young man 6 years of ag who was admitted to the service in

November 0.4. The patient had been troubled with coursels noctume at times since a child had sirely passed units from two openings, one in the normal position on the glass penis and one in the framum. Most 903 a small lump appeared on the center of the ventral surface of the penis. It was cut down upon and a stone one-half inch in diameter removed from the urethra. The slaus still remained About six months later a perincal section was performed. This opening also refused to close.

Physical examination showed a well-developed bealthy young man 5 feet to inches in height weighing 150 pounds urinary meaturs normal in suze and position sinuses, three in number one at the fremum one about 15 inches from the fremum of the ventral surface of the penis, and one i the

perlucum.

Rectal examination showed no abn trailities. Year of the utilizity tract was negative for sione Cystoscopic examination revealed a normal blad der with a small sacule into which the right ureter opened. The phetoisulphocephthalein output was normal

Exploration with probes and sounds revealed the effective of a urefun apparently normal except for a slight strict re in the bulb admitting a 5 F sound. Of the three fixtuite the posterior periods one opened into the membraneous urefun just behind the affecture. The other two t the first mad near the servium, opened int a common passers which readily took a 5 F sound a distrete the urefun; in the bulb just in front of th strict re.

The periodal sinus was excised and it opening to the membraness refine closed. The subjacent canal was allt from the fremum t the bulb It was found to be lined with a med sucrounded with its companion urethm by a common corpus spongioum. It was cumpated completely from the bulb forward. The wound healed by primary intention, and the patient left the bonyitial passing all his urine through the normal.

presser

The male urethrs originates from two genetically distinct portions of the embryo, the prestatic and membranous portions resulting from the regential simus, while the remaining portion originates at a later period from the folds of the gential ridge or tubercle

There are two important points to be settled according to Lebran () Is the absormal casal a unethm or merely som diverticular or canalicular excretory formation? (s) Granted it is a true urethm, how is it formation to be explained? Mis Kent is so chisdons after studying a large

number of cases are briefly as follows

The occurrence of more of less complete duplication for the mal rethrs, involving the canal from the boilb to the meatus, cannot be doubted, as a larg number of well-authenticated instances of several degrees of the anomaly have been recorded. Accessory canals have been described as being about equal in size to the normal worthers and freely communicating with it in the bulb as in Messels and the author case in other more passage we made in continuous transfer of the continuous c

Calcult were not found in any of the vestcles examined by the author and from his experience he does not believe that because $u \lor \neg v = 1e$ is nodular it is necessarily tuberculous II L SASPORD

Plagaemeyer II W Tuberculosis of the Seminal Vesical and Epidldymis. U J C / Re-

Tuberculous infection in the genito-unnary tract is as a rule secondary to a focus elsewhere in the body usually in the lungs intosines or bones Primary tuberculosis of the genital tract has been demonstrated by a number of observers.

Guisy in 183 cases of urogenital tuber rulosus found to eases involving the prostate and seminal resides alone. Saxtorph in a series of to cases noted of such occurrences. Walker found that the disease was stated to be primary in gento-unnary organs in 52 out of 1 4 cases, but he found in experimental infections that the lungs were nearly always involved and showed the most advanced process.

Generally speaking genital tuberculous is rare before the fourth month the percentage increasing to a maximum in the third and fourth decade

In early life both sides are often affected but after 12 the majority of cases are unlateral In Barney a series of 153 cases of epididymal toberculosis 55 per cent were right 35 per cent left and 30 per cent bilateria.

The great mass of evidence points to the ejididy mis as the most common seat of primary infection in the genital tract. Cabot says. We should recognize that urinary tuberculosis is primary in the kidney and genital tuberculosis primary in the pididymis. Walker found in 170 cases that the kidney was first involved in 184, the epididymis in 80 the prostate in 6 and the seminal vesicles in Keyes holds that the weight of evidence goes to show that in many if not all cases the prostate or vesicle is tuberculous before the epididy mis becomes so. There is much authentic evidence that the epididymis is in most cases affected hist.

Whether the normal seminal vesicle can harbor the cast-off tubercle bacill without being affected or whether its secretion has a deletenous influence upon these organisms is as yet an unsolved problem.

Considering the ranty of primary infection of the seminal vesticle and the developmental analogy of the seminal vesticle and the unnary bladder the method of attack upon the kidney in bladder thereulosis suggests the same rule in the vesticles and epiddlymis

Much argument and many experiments have been put forth to prove extension of infection in each direction via the vas some holding that extension can take place only in the direction of the current and others that a reserved parastatult is produced by irritation. Ascension by the subeputchial lymphatics and the blood stream helps to explain the passage of the disease upward without general lavolvement of the vas. Ascension seems to be the rule descension the exception.

When tuberculous involves the epidi lymis above epididim ctomy should be performed. If both pididymes are involved double epididymest my is influeted. Masculinity is not impaired and sterhly the usually already taken by

It is quistionable it or hide tom'exerisindiated When both epididimes and textes are in 1 ed it i better to incise and drain. The removal of a massivity involved vus it advisable at all is best done by the high operation of Cabot. Kemoval f the epididymus and contiguous pertion of the values has had a signal effect on the process in the villes, the infection receding and the vesi les becoming throus

If the prices in nined to the vest lenvest ulectomy as advocated by Young is a splendid operation but it the prostate also is involved it should not be reformed.

benome

The prognosis of primary tuberculosis of the genitals in children; u utility good there seeming to be a limitation of tuber ular processes in all organs in children evept the meninges. In later life the tendent to wider involvement is a trong argument for radical operation.

Hygienic and climati treatment both pre- and post-operative is of importan c. The author taxons the Corbus idea of active immunication before correction.

The con lusions rea hed in the report of the Massa husetts General Hospital is that until the vars has elapsed no patient can be said to be cured of tuberculosis.

In conclusion genital tuberculosi in the male is a grave affection and except in the ase of children operation affords the best means of "ure

The primary focus being remo ed the survival of the patient depends on the ability of his body to immunize itself against the disease. H. G. HAMER.

Surgeal treatment of acute epiddymatis has received considerable attention in recent years. Epididymotomy is a simple operation and can be done in the office under local anxisthesia. Pain is relieved prompitly and resolution takes place more rapidly than by the expectant plan of treatment. Bild cases usually resolve fairly prompit under palliative treatment. The more severe cases justify epiddymotomy. Relapsing epididymatis not dependent upon prostatic seminal visicles or posterior urethral infection are most successfully treated by total extirpation of the affected epiddymid-

feute deferentitis usually yields to palliative treatment and rarely demands surgery except when aboess formation takes place in which case drainage should promptly be instituted.

The inaccessibility of the seminal vesicles and prostate has prevented more frequent use of ur gleal measures in acute conditions of these organs.

92

On this account palliative measures must suffice in the milder cases, nd surgery be reserved for cases of well-defined abovess. Fuller incision or that of Young and Squier will be necessary to reach the vesifies, while a slight modification of lateral lithotomy will be sufficient in the case of

prostatic abcess.

N no-perative treatment of acute prostatitia and vesticulties facteds rest in bed pulcation of heat by means of the psychrophore, restricted dix antipyretile. All urethral manipulations aboutd be omitted except catheterization when exembles occurs. After excite symptoms subside massings is indicated and in the declining stage than the control of the posterior urethrar are of effoliate white.

Irrigations of the vos, ampulla, and vesicle with argyrol or protarged by Belield a method is helpful in those cases where much debris is expressed by massage. In perivasiculitis with impotence not improved by massage or irrigations through the vas, a carefully performed vesiculotomy sometimes.

will restore the sexual function.

Gonorrhoral arthritis is relieved in many instances by non-aurgical measures, but vericulotomy or vericulectomy may be necessary for permanent rehef in some cases. Vaccines, bacterial derivatives,

and phylacogens have been generally disappointing Th conclusions are Epiddiymotomy represents a decided advance in the treatment of acute cpiddiy mids. Dilastation, missage, and irrigation will benefit and control the majority of cases of prostatovesiculitis. Irrigation of the vesicle through the vas in properly selected cases is curnive. Vaccines have some brilliant successes: t their credit, and should still have a place in the treatment of these disorders. If G Hasra.

Silverberg, M The Prognosis of Prostation. Cal f St J Hed 0 6 is 60.

There are two methods of d termining the con dition of the prostntic gland () its palpation through the rectum and (a) the gross and microscopic examination of the fluid expressed from the gland. He states that the palpation of the diseased gland may be misleading in that it may be perfectly smooth and of uniform consistency but is usually slightly more securitive to touch than the normal prostate Irregularities in the size and shape of the gland are relatively common and are hard t inter pret. In the microscopic examination of the expressed secretion the presence or absence of puscells and their relation t the number of lecithin hodies present should be noted. These findings are subject to the following errors (1) the distribution of the pathological elements may be neven and the material used in the examination may be from the normal portion of the glo d likewise the marked involvement of a small focus may furnish enough pus t diffuse throughout the entire specimen and the error would be made of diagnosing a diffuse disease of the gland whereas in reality there is

present only a small focus of disease. The third factor in determining the prognosis is the reaction of the patient to the various treatments.

The author states that these co ditions some times clear up without restinent but usually do not. Most of the cases persuit with marked obstinacy. He states that fire a given method of treatment has been used for a few weeks if the particular does not improve the method aboud be bedeninged eather in whol or in part and this plannable aboud be persuited in until method suitable for that portficular case is obtained. The author summarizes as follows:

It is desirable that prostat the be cured in every case but treatme t f equently fails o is otherwise

unsatufact :

The outlook is a important matter to the individual as well as from the tandpoint of social hygnene prophylaxis.

The probable same is supported by the history.

3 The probabl same is suggested by the history clinical findings, and by closely f llowing the effects of treatment

4 There is really no scientific method of establishing prognosis, though bact roology may avail here
5 The duration of treatment is uncertain.

\ D Level use

McCarthy J F Som Features of Importance in the Diagnosis and Prognosis f Urogenital Tuberculosis. Surg G₃ α = Ob t = 0.6 mm tu 330.

The author calls attention to the importance in urogenital tuberculosis, of a vestigating the deep urethra as well as the bladder. He comments on the frequency (hithert insufficiently emphasized) of the associated involvement of the rethral structures even in the presence of unilateral renal to berculosis.

Attention is also called to the fallacy of operative procedure such as epididymectomy etc. without the most careful inspection of the posterior urethra.

The author feels that will it is generally recognized by unodoptical surgoons that operative intervention such as nephrectomy etc for t berculosis should be reparted merely as the preliminary step in the treatment of a constitutionally t berculoss subject sitogether too little emphasis is accorded this f c tin operative chinks as well as the hospital care of such cases.

Finally he emphasizes the supreme importance of universal tate care of the surgical tubercu lous, non-operative and post-operative subject, from the economic and humanitarian standpoint

Verhoeff F II Rosaces Keratitis and Certain Other Forms of Marginal Keratitis, Neuroothic in Origin; Treatment by Pericorneal Neurotomy Arck Ophile, 96 ml 148.

Not generally known is the fact that with acute coryza and gastro-intestinal disturbances, herpetic lenous limited to the periphery of the corner and of

a highly distinctive character may occur

The utho contends that as they are uniformly

located 15 mm. from the limbus this shows that they occur at the terminations of the conjunctival nerves in the cornes, and lexions situated 3 or a mm. from the limbus are explained by assuming that some nerve branches extend unusually far

Since it is generally accepted that facial herpes is neuropathic in origin, it is regarded as altogether probable that these peripheral corneal lesions are likewise so and the author's explanation of neuropathic keratitis in general is that impulses from the affected ganglion cells pass backward along the ordinary sensory nerves to the nerve terminations in the corner where they produce by electrolytic dissociation, toxic substances injurious to the tissucs.

Rosacea keratitis is also researded as a form of neuropathic keratitis, and acting on the above theory the athor does a partial perit my to interrupt the injurious impulses, with the result that in fifteen cases operated on during the past year he has secured prompt healing in all, with no recurrences.

Rosacea of the akin, bel g regarded as an angloneurotic condition due t some abnormal constituent of the blood he correlates with the corneal lesions by assuming that the same deleterious agent cts on the gasserian ganglion and through this on the S. S. Hown akin and cornes.

Deboques, T. L. Treatment of Gonococcic Con-

junctivitia by Autoconococcic Serum (Trata miento de la conjuntivitia blenorragica por statro antigonocoraco) Res & med y car de la 9 6 Ext 99-

The author reports 8 cases successfully treated. The first hypodermic i jection of the serum con dated of ccm. Subsequent injections of a ccm. were made every three o fou days. After the fifteenth day of treatment no gonococci were found in the secretions. Corneal ulceration was found in one case, but was slight and yielded to special treatment. There were no phenomena of anaphy lards and no nervous symptoms.

TV A BREWAY

Smith, S. M. Aural Complications of Influenza Theres (see 0 6 al, 05

Otitic influenza lik other inflammatory changes due to the bacillus of influenza is distinguished by the intensity rapidity and virulence of action frequently in olving the mastold and other adja cent structures, with beence of the usual symptoms. The initial observable inflammatory process is a severe myringitis, hemorrhagic in character with spontaneous ruptur of the membrana tympani in forty eight hours. Early free inclaion of the mem brana tymponi with rest and general eliminative treatment are the best prophylactic measures.

ELLIN J PATTERSON.

Packard F R. Report of a Case of Acute Mastolditis, with Influenzal Meninglitis: Treat ment by Operation on the Mastold and Anti-Influenzal Serum. T is Old Sec Washington 9 6 M v

The patient a young girl eleven years old, following severe chilling developed what was apparent ly a grippy att ck a d an acut otitus media in her right car The author incised the membrana tympani and evacuated some pus and the next day she had distinct symptoms of a mastold involvement, accompanied by some at po marked Kernig sign, photophobia and muscular rigidity of the neck. The mast id was opened and at the of the neck. The mast id was opened and at the same time—lumbar puncture was performed. The fluid withdrawn from the spinal col ma showed an influenzal bacilli. Flexner' anti-influenzal serum was injected int the spanal column. Several such injections, each of which was followed by marked improvement in the patient's condition, were used in the course of the week subsequent to the mastold operation and the development of the meningeal symptoms. The child's mastoid wound did well, the meningeal symptoms practically subsided and marked drowsloess developed with a recurrence f the symptoms of meningeal irritation The diagnosis of abscess f the temporosphenoidal lobe was made and the cranium opened and pus evacuated. The ch. then made an uninterrupted recovery

Dench. E. B Acut Mostolditie with Unpeual Symptoms Indicative of Intracranial Involvement; Operation; Recovery T Am Ord Sec., Washington o 6 May

The patient, a young woman aged 7 was operated upon for mastoidiths on the eighth day after the inception of an acute otitis media. The mastoiditus vas jound to be of the harmorrhagic vaniety. Convalescence was slow and six week, after the operation the patient was again admitted to the hospital suffering from severe h ada he gen eral neura themic symptoms and ment 1 depres i n At this time there appeared also an abducen paral yas upon the affected ide. Ther vas no evilene of of any labyrinthine involvement and no aphasia the spinal fluid was negative and the ophthalmoscopic examination showed ea hocular juntum

On account of the se ere haida he a large area of dura was exposed in the mid-lie ranial tosas and the dura stripped up from the doro of the middle fossa as far as the ages of the petrou. I rampi No extradural ollection for put was found and no collection of pus was found and not collection of pus was found in the old market if word ache immediately disappeared and the blue en paralysis disappeared. A rub bert to us frain had been increted leep in the middle remail tosa at this operation. There also such that per the prattim swelling of each optic papilla was not red—more marked upon the operated adde. The rub bert it used that was removed and the pit neuriti rapidle disappeared.

While the case presents many f the ampt ms first described by Gradenigo it differ from them in that in these cases some purulent socus ha, usually been found at the time of operation, the presence of which explained the symptoms. In this particular case no such focus was found. It seem probable to the author that the cause of the unusual symptoms was a low grade of inflammation spreading along the dura to the apeton by practice and as an area of dura in the mill lossa was exposed at the time of the mass of operation. This metangeal inflammation prob bic caused a certain amount of pressure upon the gasserian ganglion and also upon the sixth nerve causing the severe neuraling pain in the head and the paral is of the sixth nerve.

This report does not deal with cases where the diagnosis is we evident that it can be made by a glance at the patient but rather with those cases in which the development of the inflammators process is so insidious and the symptoms so slight that a diagnosis is made with the greatest difficulty.

The author reports several cases in which the middle-ear condition had deared up or was rapidly clearing up but in which the inflammatory process in the mastoid was rapidly progressing as was demonstrated by the operation. From such cases the author draws the on lusion that the actual cessation of discharge is no absolute indication that the mastoid i health? Su h being the case the

author attempts to show how one can tell in a given case or a rute aural suppuration that there will pr bubly be serious mastoid involvement or how one can tell in a given case that any involvement has entirely disappeared when the middle ear has rung tell erco ered

The filling diagnostic signs are mentioned it is the sit of the inflammatory process the author tates that inflammations confined to the lot error of the timpain cavity are much less halle to be followed by sin us mained infection than cales in which the upper part of the cavity is involved:

As t the durain not the discharge the author beheves that muddle car involvement hich doe not r she ern i mutel at the end of two weeks is one i mait if involvement sun i nily extensive to d mand at least explication person in

3 C n rning tendernes in pressure over the mastoid the authoritates that tenderness at the beginning does not mean much but tenderness after the furth or fifth day is of great significant and he add that tenderness over the antitum is of more significance than tenderness over the tip

4. The nature of the discharge is of importan e s a streptoco. Us infection is more likely to result in masterid infection requiring operation than is a taphyloco, us infection.

The sign upon which the author places most reliance is a narrowing of the external auditory meatus near the frum

6 Another important anal sign is an actual shortening of the external meatus a condition in which the entire drum membrane appear hearer to the entran e of the canal than under normal conditions

The above signs acquire additional importance where the opposite canal is normal in caliber and length. Concerning the swelling of the canal aused by furun uloss the author notes that this narrowing is more supern tall than the narrowing due to may told involvement. When in doubt the author opens the mastical.

- 8 Roentgenograms are mentioned as of great
- o The general symptoms mentioned as of diag nosti importance are persistent headache and sleeplessness
- As to temperature and the differential blood count the author is not much influenced by their
- In closing the author cites a ase illustrative of the diagnostic importance of recurring attacks of acute of tits in pointing to mastord invol ement. The author feels that this sign needs more careful consideration as he argues that these arts as would not recur unless a purulent focus existed somewhere in the deeper stru tures of the middle ear.

SURGERY OF THE NOSE THROAT AND MOUTH

MOSE

Vensey, C. A. Th. Diagnosis and Treatment of Inflammatory Affections of the Nasal Accessory Sinuses. National Med 0 6, x7 71.

After alluding to the importance of sinus disease as a causative f ctor | many gastro-intestinal af fections, as well as t vernias affecting ther portions of the body the auth considers the sinuses collectively and mentions the well known symptoms of beadache, tenderness, nasal obstruction and discharge dizzines and vertigo as well as prosevia and neurasthenic symptoms in general.

As to diagnostic methods the th mentions transill mination as one of the best axis. Other aids, as the pharyngoscope X-ray puncturing ad irrigating the antrum and the application of action to the nose ore favorably commented noon

As to treatment of the acut condition, the uthor mentions the ecessity of securing adequate drain age and ventilation and this is secured by shrinking the nasal mucosa by the application of weak solu tion of cocaine instead of adrenalin, as the latter is ant to produce a secondary swollen condition greater than was primarily present. After the membrane has been shrunken, the author cleanses with a ormal soline solution or with mild alkaline solution followed by an application of a as per cent solution of argyrol and a oil spray Th patient is instructed to douche his pose freely with hot normal saline solution every hour o two and to take deep inhalations every two or three bours of compound tincture of benzon and menthol, four ounces of the former and ne drachm of th latter, two tablespoonsful being used in one-half pint boiling water General treatment with calonel, saline aspirin and phenacetin is recommended.

The I dication for the treatment of the chronic cases is likewise drainage whether obtained by the correction of obstructing septal deformaties or hy pertrophied turbinates. After drainage has been obtained irrigations re advised and when these prove futile operative interference is justified. The utbor has little faith in the beneficial infl ence of OTTO M. ROTT

autogenous vaccines.

Gatewood, W. E. Carcinomata of th Naso-

pharyna J im M An 9 6 lol 490 From a review of the literature, the following

points are gleaned

Carcinomata of the pasopharynx ar characterized by a rather loos latent period and most of them originate in the vault or on the posterior wall. They are more prone to ulcerat and lead to enistaxis than other malignant tumors of this region. Extension may take pla in (ru w vs. () by the inferior or pharyngeol out (1) by lateral prolongation (1) by the anteri or nasal rout (4) by th posterior o cranial route

(arcinoma)

f the nasopharyna very rarely produces viscer I met st ses but as rule they give earlier adenopathy than other t more f this region About 60 per ent of the carcinomat in this end on u i individuals between 4 and 60 years of age b t they ha bee oticed in hildre OTT M POTT as young as 3 6 and

thor report case of true papallary fibroad in a alored woma ged 4 which had been of years duration and pre sously operated pon. When first seen by the thor the left nostril was filled with a gro th wh h presented dry da k, and wrinkled ppearance. The nasal cavity was so completely tilled with the growth that a snare could not be passed round it much less the sit of origin determined. To flect remo al biti a forcers was used and thus it origin from the lowe border and ext mal surface of the middle turbinate was determined. M croscopical examination revealed the nature of the gr wth. Of particula interest was the ppearunc of the epithelial cells which retained their columnar character even to the surface. Other features of interest in the histological sections were the intense purulent inhitration of the epitheli m nd it absence from the connective-trisue stroma, the pus-cells in places offecting I to groups ad forming cystlike paces.

The growth had a tendency to recur so in order to eradicate as thoroughly possible the base of orien and hence to evert the da ger of malignant change the author intends performing a Caldwell Luc operation, followed by a radical Mosher operation. After this careful cauterization of the tismes with a chemical substance such as trichlora Orno M. Ratte cetic ackl will be made.

Dabney V: Deaths Attributable to Intranasal Operations and Other Instrumentation Surg Grace & Obst | 016 xxii | 324.

Deaths following cauterization of the nasal mucosa diagnostic nuncture and irrigation or mere perflation of the antrum of Highmore are not to be expected but it is surprising that more deaths do not follow probing of sinuses resecting the septum or removing the middle turbinate in part or in its entirety I olypi removal is more danger ous than believed for the same reasons as they indicate deep-seated disease and periostitis. In fection is accounted for by the virulence of the bacteria opening wide spaces for absorption of toxins trauma and continuity of tissue. The lymphatics rarely transmit infection which travels by the blood stream or by actual continuity as a rule. Cocaine was not responsible for any deaths though adrenalin was. Numerous authors are cited to show that adrenalin with light chloroform angesthesia is neculiarly dangerous, even with light etherization it is thought risky. Deaths due to adrenalin were 4 to hiemorrhage 3 to packing nose for epistaxis I to puncture or injection of air or fluids into the antrum of Highmore 10 to probing and irrigating frontal sinus 3 to polyp removal a to ethmoid curettement 4 to turbinate operations o

In the author's personal case f llowing resection of the lower edge of the inferior turbinate of one side the patient never recovered consciousness from the ether and died in three days from cerebrospinal meningitis. It was probably a case of latent meningitis before operation. One death was due to exploration of the sphenoid sinus o deaths resulted from resection of the septum Deaths from invasion of the antrum of Highmore are due to reflex irrita tion of the vagus through the irritation of the second branch of the trigeminus which upplies the interior of the antrum It is demonstrable that the interior of the nose is a zone of considerable danger for even the slightest instrumental interference and that adrenalin combined with a general anaesthetic especially when used for operative assistance is not to be lightly employed.

Blackburn W J: Submucous Resection of the Nasal Septum J Ophik Olol La II

The universally gratifying results in a series of over a hundred operations for submu ous resection of the septum leads the author to conclude that a deviated septum may be the underlying cause of many diseases of the nose horoat and car. By obstructing the masal respiration the resistance of the tusiues of the nose a di throat are lowered and patients with diviated septa frequently develop ethinolitis sinusitis suppurative of the media mattorlitis with train absects laryingiti bronchiti chronic heads he deafnes tinn tu aunum authina hay few or other neutrotic conditions.

liur JPπ aso.

Sluder G A Galvanocautery Operation for the Lower Turbinate Lay 5 opr 9 6 xx 1 66

The pathological condition for which this tech nique is recommended is general swelling (hyper troph) or intumestence) of the soft parts covering the lower turbinates the chinical condition being for the most part nasal obstruction with or without estachian time irritation.

To the anteroposterior incision usually made in cautemzation of the inferior turbinate, the author has added (1) a straight one descending in front at an angle of 45 degrees from a point a little above the line of attachment of the body of the turbinate to meet tangent the anterior limit of the anteroposterior incision and then descending below it to the level of the free margin of the vestibule almost to the mucocutaneous junction in the vestibule (2) two curved incisions on the body of the turbinate posteriorly which are made operating from the postnasal space by means of a specially curved autery tip introduced through the mouth behind the soft palate. One curved incision is made above and one below each beginning 1 to 1 25 cm in front of the posterior tip and extending backward to meet on the lateral wall just at the tip (3) the tip of the autery is extended forward to a point which is to be the posterior end of the anteroposte nor incision and carned backward over the tip to the junction of the curved incisions or even as far backward as the cartilage of the anterior lip of the mouth of the custachian tube especially in those cases associated with tubal irritation

For all this work the author uses an electrode which has no insulation upon it and which consists of the two opper wires which are united by a flatino-ridium up. This permits the wires to be separated and spread apart as far as I cm if desired which transforms the narrow up into a V or U shaped end as desired. When this is used on the pull any tissue to be removed can be engaged in this loop and the current turned on, when it acts like a stockeshave.

The author has a definite order of procedure in this work which is as follows

After anaesthetizing the turbinate and soft palate the latter is forcibly drawn forward by the author s self retaining palate retractor \ \large warm post nasal glass is used as a tongue depressor curved electrode is then introduced cold in a hor izontal plane through the mouth into the pharynx. The class is then slipped back into the postnasal position and the tip of the cautery is brought forward into the affected nostril put in place and the current turned on First the lower curved incision is made next the posterior end of the anteroposte nor incision and then the upper curved in is on. This comil tes the wirk from the postnasal side Fr m in fro t the author introduces a str ight tir to meet the middle posterior in ision and arries the torward until he reaches the anterior end of the incisio wh he hanges the direction of the tip pl cing it near the interior to f the middl tur

binate, when it is drawn downward and forward to its prescribed lower limit. The tip used is so h t that if it were once removed from the manue it would burn itself out.

The author has employed this proced re in more than noor cases extending over period of seven-ten years. Out of this number 3 cases required an anterior packing with Simpson a guillain to control bleeding. In more of the author's saars and existent operations has the result been so satisfactory as with this method. The author has never seen the permatent drying or crusting mentioned by some men. This method is also applicable to sunt my off the posterop raid of the inferior turbinate.

Two cases are reported in which designess, not exponding to any of the operations for nasal obstruction, has responded to this method of cauterization especially when the posterior line extended to the anterior tip f the pharyogeal orifice of the extgaching tube or 70 M Korr

Kellogt F B r'An Improved Submucous Operation J Opick. Old & Lerragel 9 6, xxli, 5

The author makes his primary incision from high up in front of the deviation on the convex sid down to and half way across the floor. Then elevating the membrane hove and below the edge of the ridge until the mucross membrane of the convex side is free except inlong this edge he inserts to blades f a delicate pair of scissors one above and one below the ridge and trims off the edge f the ridge kaving it attached to the membrane. After elevating the membrane on the concave side be linaries a Boos rib aw under the d flectuo inside the membrane saws off the projecting spar in the plan of the septem removes the spur with forcept, and packs with trips of spank.

THROAT

Haya, H. A Simple Tonail Operation Under Local Ansetheda. Med. Rec. 9 6 ltd 4 9.

Using Schleich infiltration anesthesis the author depresses the tongue firmly and separate the torsil capanie from the netroir pills working from the below up with his double bladed kaffe. Then using his modified aneurism needl threaded with stout cord or string, he threads the cord in the deepest part of the tonsil from below upward ties it and using the cord as a retractor completes the dissection with Hurd tonsil separator or the finder. Eurey J Partrasson

Shearer T L. Th Question f Ag in Tonsillectomy J Ophth Otel, & Laryngel 9 6, xxil, 205

Toraillectomy is indicated in adults under of vears, when the patient has hypertrophied or diseased tomals or the tonals are the focus of infection of pathological conditions remote from the tonal. It is indicated also in malignant disease of the tonal Irrespective of age followed by radium radiation of the wound.

Tomsillectomy is contra indicated in any adult flering from arterioscherous, and dults over 45 are treated satisfactorily by the electrocautery ELLEN J PATTERSON

Friedberg, S. A. Removal of Tonells and Adenoids in Diphtheria Carriers. J. 4m M. 121 9 6 lvt. 6

Several instances have been noted in which the local application of knolm seemed to be without any effect on dipthers bestill. In view of the prompt dangipearance of the bacilli in these cases after totallicationy and removal of adenoids the uthor makes a brief report of the results.

Six cases are reported five occurring in children. The tonsils were removed after all methods were used to rid the throat of diotheria. I two days

o less the cultures became negative

In note of these patients did the operation have any different general effects than it has ordinarily In all of the patients the Schick test gave negative results just before the operation. Six successive negative cultures were required but he the patients were discharged.

The results biained in this sense indicate clearly that in penalstent curriers t may be eccessary to rem ve the tomais and adenoid tissue f it is desired to terminate the carrier condition promptile.

The bacteriologic examinat o should be made with care as it is well known that applications of medicinal agents may destroy the bacill it and caveling leaving unaffected those in the crypts of the tonsist and the folds of the add of those As to the time the operation hould be performed it is pertains advisable t in it from two t three weeks after the clinical recovery of the patient. In the case of the chronic carrie no time limit is Decessary to the patient. Departure of the control of the contr

HIJOM

Durante, L. Tuberculous of th Tongu , Serr Phile 9 6 bhs, 43

In addition t reporting 5 cases f tuberculosis of the tongue, the author gives very complet biblion raphy f the literature pon this unusual disease. H has been able to collect bout 250 cases, some of which, however hav been recorded without and tomicoclinical details. The reason for the relative in frequency of the lexious on the tongue an organ which comes in contact with almost all tuberculous infecting material, is due probably t two factors (1) to the particular structure of the lingual mucosa which resists the direct penetration f the bacillus tuberculosis and (2) t the natural resistance which all struted muscle presents to the lodgment of the bacilli. Almost all of the cases cited occurred be tween the twentieth and fiftieth year a d n case has been recorded as occurring in infancy the ago in which tuberculous lesions are so common and widespread From these considerations the author concludes that the tuberculous process in the tongue

is assisted by such lesions as trauma of the mucosa by pipe stems, by canous teeth by torne glossitis etc., and that as these causes are more frequent in men than in women lingual tuberculosis is to be expected more frequently in m n * *tatisti bear out this contention as Chvostek reports one w man to every four men and Delavan records ne in

twenty three While theoretically tuberculosis may be localized in the tongue by the blood vessels by the lymphatics by direct infection, or by extension from surround ing organs practically it is impossible to determine the exact method of infection. Many of the cases reported in the literature as primary tuberculosis were not controlled by autopsy so that the term must be accepted in the clinical sense only. The theoretical possibility of a primary tuberculosi of the tongue is practically confirmed by two cases which the author collected in which the patients died from other causes and careful post mortem examination gave no evidence of tuberculou infection in other organs. In the majority of cases, the localization was secondary to a tuberculous proces lsev h rc in the body. From the histologic examination of the tissue removed from the fiv patients report 1 by the author and from the statisti's cill cted by him the indications all seem to point to a harmat g nou infection as the most common in third of infection of the tongue by tuberculosi

The anatomical forms of the disease in not reresent a distinct anatomical entity but div rie forms of the same evolutionary process depending upon the virulence of the bacilli, the local r sistance of the tissues, and the systemic resistance of the patient, are found in various cases and in various parts of the tongue in the same case ning is always characterized by new formation of tuberculous nodules which may be localized sepa rately in the dermis of the mucosa or in the lingual parenchyma From this initial localization of the tuberculous process two clinically different types may originate. The first presents itself initially as a plaque of gray color somewhat elevated above the surrounding mucosa hard to the touch and without inflammatory reaction It resembles cutaneous lupus and is very often accompanied by lupous lesions of the buccal mucosa of the nose or of the skin of the face This type is referred to as glossodermatitis tuberculofibrosa or should it ulcerate as glossodermatitis tuberculo-ulcerosa When, on the other hand the parenchyma of the

tongue is primarily affected nodular tuberculous may result or the lesions may become confluent or disseminated in various regulas-disseminated miliary tubercul sus of the tongu. The second type in any of its various f rm may maintain its ana t mic individuality for month, or years simulating ither a neonlastic lesion or the localization of t retary lues. The typical tuber ulous ul er has irregular margins inu u soft and reddened with a wit vellow base. It my ppear in any region t the tongue but with m re frequency on the margins and the tip. The adentit, which accompanies it is often bilateral and lightly painful to pressure. Usually thire is not much difficulty in unding the bacillu in tuberculou glos itis although and alted case hase be n reported with at the In illu being fund

The emptoms vary on, iterally with the tag it evolution in the listage. The initial period is narked with few or no subject is symptoms. When the ullerative it may lope the reliable abundant livation and some pain du mostly to the passage. It had the pain may limit the mibility fither ingue. In the ulterative type, which is might attend to see on fairly infection there is usually painful gir nat a den pathy liut in the closed from fingual tuberculos in it iten alsent.

Digress in the early type of the process present great dain ulty. Mistak in tor-pithelomatous mopilasms amputations of the tongue with radii al remo al of the glands or the neck have been done for tuber ulou glossiti. Mer unal treatment has be n.emplay in 180 reported assesshowing the frequency with with it has been mistaken for tertiary lues. There are no ure entertia of differentation and it is always well in cuse of doubt to employ the microscopic examination of the tissue of the lesson. This can usually be done by frozen sections during the operation as was done in each of the cases reported by the author.

The prognosts is favorable when the tuberculosis of the tongue presents itself as a primary and unique lesion. It is generally unfavorable when the lingual lesion is a late localization secondary to a bronchopulmonary process

The treatment of election which has been avoided by previous authors has been operative when the tuberculous lesion of the tongue was single and circumscribed. In the multiple and diffuse lesions the treatment recommended has been local with the cautery.

DAKINS NEW ANTISEPTIC

This interesting antiseptic was introduced by Dr. H. D. Dakin, who was associated with Dr Alexis Carrel t the temporary hospital No. 21 and th Isboratories of th Rockel ller Found tion in Compleme, Fance Reports show this antiseptic is being used with great uccess in the military hospitals of Europe (See British Medical Journal of January 29 1916, Reprints on request.)

CHLORAZENE promises to be of great value in surgical practice Read the following statements and it will be understood why this new antiseptic is regarded so favorably in Europe

It is a widt constalling anhatency freely soluble in water

It is extremely stuble, I c., in solid form it may be preserved indefinitely while acraeous solutions keep for relatively long time thout marked decomposition.

It has no correctes action, even in concentrated sol tions. It neither precipitates nor congulates proteins such as blood serum

It is sirtually non tracic. Rabbits and guines-pigs tolerate subcutaneous doses of grams t kilo (2.15 pounds) of body wight. In no ymptoms except moderate local reaction. However, t about how the use duriernally

and the state of t Its antisoptic action is interest. It is many times as anti-optic as phonol equaling

It can be used fronly and refoly so an irrigent of infected wounds of deep theses, in treating compound fract res and m number and diseases of the month aterus, bladder no uretura here most antropts, cannot be employed in effective concentration on count of their toxic or caustic action

In view of the success which has followed the use of this intiseptic in Europe. The Abbott Laboratories offer it to the medical profession of America under the DAMMA CHILORAZENE ABBOTT

but no Pulmotor was used!

The mistake of confusing PULMOTOR with the device that was used is natural.

In 15th years the nam PULMOTOR has tamped teelf and libly upon publi consciousness, through the present theoretic mannels of information in when the schierem not ofthe number of the man life has been recorded.

Unhappily the new paper running the ritel reproduced on thi page referred to PULNOTOR the resuscitation device responsible in painful injuring inflicted in the persons by the bursting of need container.

Not only was no PULMOTOR sed in this instance but had the PULMOTOR been used the accident could not have occurred.

The PULMOTOR employs no send as its operation. Its action depend upon the force of compressed oxygen in an oxygen exhader. I combines not only the neutrance of no layery being done to be patient. Inner because of its physiologically current primaphs, but natures the entire of the operators as well,

WATTERS CHLOROFORM CATGUT

Experience vs Experiment

When considering the choice of Catgut, remember that

Watters were the first to preserve Catgut in Chloroform in 1904 Since then practically every man facturer has fillowed our lead.

Watters were the first to employ a stable sodine compound to rend r catgut <u>Antiseptic</u> as well as <u>Aseptic</u>.

It has taken others years to recognize the wisdom of our pioneer work

But Catgut put up in Chloroform is not CHLOROFORM
CATCUT

Newer Blood Tests

for Rheumatism, Arthritis. Gout. Nephritis, Uremia and Diabetes

In diabetes it is desirable to determine the sugar content in the blood since this may be high while the glycosuria may be low owing to in efficient kidnes function. In diabetes with acido is the carbondioxide determination is useful since any considerable increase indicates a grave condition

For differential diagnosis between gout arthritis and rheumati.m the estimation of uric acid and non protein nitrogen in the blood is of assist ance In gout unc acid only is increased in arthritis both the uric acid and the total non-protein nitrogen are high while in rheumatism both are normal. Hav Fever: Adrenalin

The suprarenal substance, in the form of its isolated active principle Adrenalin, is the chief reliance of a host of physicians. And well it just fies their confidence. Adrenalin effectually controls the nasal discharge. It cuts short the violent sneezing paroxysms. It aborts the annoying lacrimation. Nasal obstruction disappears under its use. Natural breathing is resumed. Distress gives way to comfort

I Wri g to Advertisers Mention Surgery Gynacology and Obstetrics

1866-1916

Golden Anniversary Announcement

To the Physicians and Surgeons of the United States

We extend a cordial invitation to visit our New Home when in Philadelphia

We shall exhibit, at the Meeting of the Clinical Conpress of Sur geons, to be held at the Belle ue Stratford Hotel many new instruments of novel design devised and used by operators in the various clinics.

For fifty years we have maintained the enviable reputation known the country over of making Superior Quality Surgical Instruments Cautery Knives Current Transformers and Appliances for the Correction of Deformities also as dealers of furnishing the highest grade of electrically heated Office Sterilizers Steel White Enameled Office Furniture Electrical Apparatus and Accessioners.

DR CHARLES GEIGER'S

Electro-Operative Surgical Bone Instruments and Accessories

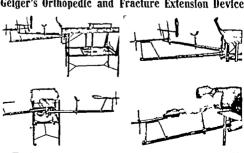

Used and recommended by Dr. John B. Murphy Dr. Fred H. Albee, and Drs. W. J. and C. H. Mayo

This set of instruments is especially mad for transplantations, dowel making and cranial work, Wat is not equired to keep the cutters from burning the bone, in using the Geiger machine, because of the slow speed. A few of the many advantages not found in other motor bone instruments are: Sterilization of the motor slow speed. great power simplicity of the chuck, and the firmness with which it can be held

Dr Charles Geiger's Orthopedic and Fracture Extension Device

m kes orthopedic and fracture work casy for the sur geon gives dear ance and emoves ll obtuton wh l applying c t o unget hip o back or any part of the limb Per fect and continu ous extension can be mad on the emallest child as well as the largest man The operat ing table is not in th way while p plying dressings to the extrematics as found in all other

This device is portable, and can be quickly attached to any operating table.

DR CHARLES GEIGER.

St Joseph Mo., U S A.

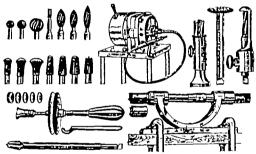

During the Seventh Annual Session of the

Clinical Congress of Surgeons

At Philadelphia

WE will, as has been our custom in former years have for your inspection a complete line of operating instruments apparatus, etc. for every branch of Surgery

You will find here instruments of special pattern made according to the exacting requirements of their authors

One of the items of special interest which will be shown is our

Universal, Noiseless Bone Surgery Equipment

with instantaneous stop hand piece. This engine can be used for bone transplants cranial antrum sphenoid frontal sinus and mas toid operations

The Camp Physiological Belt

Employing a new principle in adjustment makes it the most efficient mechanical device yet offered to the profession as an aid to the replacement and support of the abdominal viscers in the treatment of both operable and non-operable cases. It has been subjected to the most severe tests over long period of time and has won unqualified approval. It is most efficient for two resons—

Anatomical correctness of design and construction Wonderful flexibility of adjustment

Illustrating the support pplied as complete belt worn without cornet. A regular cornet back is used in the type of belt flording complete support and distributing the present evenly throughout, bed telly preventing consertation at any por t and obvicting objectionable features of other belts.

IMPORTANT ANNOUNCEMENT

New Work

Just Ready

THE TREATMENT OF

DIABETES MELLITUS

WITH OBSERVATIONS UPON THE DISEASE BASED UPON ONE THOUSAND CASES

By ELLIOTT P JOSLIN, M.D.

Asperant Professor of Medicine, Harvard Med. al School. Consulting Physician, Boston City Hosp t. I. Collaborator to the Nutrition Laboratory of the Carnegie I stitution of Washi gron, Boston

Octavo, 440 pages, illustrated Cloth, \$4 50 net

THE NEW TREATMENT OF DIABETES—the Allen treatment 1 -by means of fasting and the importance of physical exercise for diabetic patients are fully discussed in this work. Complications are described along with their treatment. This saves repetition and shows the doctor how to handle the complication when it develops

The hopeful tone which the author's experience with his own patients has enabled him to assume regarding such complications as tuberculosis arterio-sclerosis and gangrene will be most helpful to practitioners who read this book. The section on Surgery will enable the surgeon to operate

on diabetic patients without sending them into coma

PHILA DELPHIA

705-710 San om Stre t

Under Aids to the Practical Management of Diabetes the author gives a list of the things every patient should know complete and precise directions for nurses history chart and dietary and urinary records now successfully in use in many institutions also the actual diets employed in typical groups of cases

The section on Foods and Their Composition is so arranged as to make it unnecessary for a physician owning this book to possess any other book on food values either for the treatment of diabetic or other patients Standard recipes and diets for severe cases of diabetes are given notably an appropriate diet for severe diabetic patients who are poor

No physician who has diabetic patients can afford to be without this

book

John Benjamin Murphy

BORN DECEMBER 21 1857 APPLETON WISCONSIN

GRADUATED RUSH MEDICAL COLLEGE 1879

CHIEF SURGEON MERCY HOSPITAL

PROFESSOR OF SURGERY AND CLINICAL SURGERY NORTHWESTERN UNIVERSITY MEDICAL SCHOOL

CHEF OF EDITORIAL STAFF
SURGERY GANECOLOGY AND OBSTETRICS

PRESIDENT AMERICAN MEDICAL ASSOCIATION 1911

PRESIDENT CLINICAL CONGRESS OF SURGEONS
OF NORTH AMERICA 1914

FOUNDER AND REGENT
AMERICAN COLLEGE OF SURGEONS

HONORARY FELLOW
ROYAL COLLEGE OF SURGEONS OF ENGLAND
DIED AUGUST 11 1016

An Appreciation

P. JOHN B MURPHY possessed those intellectual physical, and personal qualities which make a surgeon. After graduating from Rush Medical College in 1879 and and came under the direction of that master surgeon Billroth, then at the height of his great career. Billroth was a man of charming personality and most original mind, and his students today fill the chair of surgery in many Teutonic universities. During these formative years of D Murphy's European solvant Albert was also one of his favorite teachers. Few men ever equaled Albert's ability to logically present clinical surgery. Fired with zeal Dr Murphy's returned bome and came under the influence of the father of modern surgery in the West—Christian Fenger—who was unequaled as a teacher of surgical pathology. Dr Murphy combined the qualities of Billroth, Albert and Fenger.

The reputation of a surgeon, in the final analysis must rest upon (1) originality (2) teaching by word of mouth (1) teaching by the printed word, and (4) surgical indement

and operative skill.

Dr Murphy had a marvelously fertile and original mind. Possessing a brilliant surgical imagnation, be early deviated from the beaten paths and invaded new territory and yet with such acumen that nothing which he originated has failed to live. Like those of the great musicana, his productions are still matterpaces: they mark epochs in surgical progress. He made the experimental laboratory a hand maiden to ungery and carefully investigated every detail of his constructive work by animal experimentation before applying it to man

As a teacher of surgery by word of mouth he had, in my opinion no equal. Clear and logical, be started with facts about which there could be no dispute progressed from these facts toward new ground, yet along pathways more or less familiar to all and finally taking us by the hand, so to speak, he fed the way to new truths by the light of his surgeral remins.

As a writer be was proude. His early work was in the field of abdominal singley? The Murphy button taught in to solve many problems connected with gastro-bitestinal surgery. His monograph on "Heis" still stands a monument to his scientific ability. The history of surgery of the appendix, pelvis, and upper abdomen, as well as of the kidney shows evidences of his sentus. Dr. Murphy next developed surgery of the lungs and, in the oration on surgery delivered at Denver in 1628 he land the foundation for modern surgery of the lungs so lar sheed of his time was this that we have only of late awakened to an appreciation of its value. Dr. Murphy's work on surgery of the nervous system helped to lay the foundation for the present practice, and again his latest work on benes and joints, in which he was engaged during the closing years of his life are perhaps the greatest contributions to these subjects of our generation.

Dr Murphy was skillful as an operator of fine judgment, humane, sane, sound, and free from farls. What surgeon has not felt, on seeing him operate a just prod in the science and art of surgery and expressed the hope that in the event he or a member of his family must have an operation, so good a surgeon as Dr Murphy might perform it?

The American surjical profession has lost its leading spirit. In Dr. Murphy's death at the age of fifty-eight, well may we regret the unfilled twelve years which so to make up the allotted span of man. And yet, when we review what be less done we freely acknowledge that even in the time the light lasted he accomplished more than any other surreon of his time.

William & Mayo

Our Chief of Staff

OHN B MURPHA was the underlying support of Strgera Gynecologa and Obstetrics and the International Abstract of Strgera from the time of their inception to the day of his death. He was the inspiration for every move of ment that Strgera Gynecologa and Obstetrics has stood for and fathered. He was the adviser personal triend and aid to the editor and his associates and when difficult problems arose his strength of character his personality and his power of vision all were contributed unsparingly toward right solutions. Dr Murphy was one of the few who maintained at the first conception of the Journal that it would succeed if it were comprehensive and served the needs of the surgeon. And to this ideal he inseparably attached his program of personal energy and manacial support.

When the Clinical Congress was developed through an informal invitation of the Journal both the surprising response to this call and the far reaching benefits it offered to surgeons nied his imagination and he declared for a permanent organization. Through his force the organization became swittly the great clinical society that he predicted for it it served the practical needs of the surgeon.

When at the third ses ion of the Chinical Congress some discussion arose as to whether America should have a great society for the advancement of surgery it was Dr. Murphy who was recognized by the President of the Congress to second the proposals of the officials. On that occasion he made such a compelling appeal that every man in the audience grasped not only the great vision but also how the vision could become fact. On his motion, then the committee of nine was author ized and the American College of Surgeons ceased to be a dream and became a certainty

These three organizations which have become powerful agencies throughout the medical world were but important incidents in the constructive mind of Dr Murphy. But each of these organizations owes its existence to his enthulial tic support to his uncompromising determination that each represent fundamentals of progress in surgery which are worth while

The personal loss to the staff of the Journal is too great and at this time the heart is too full to dwell here on more than the mountain peaks of his service. The details of a wonderful association and friendship are sacred and the writer mourns the loss of the greatest iriend he ever knew.

John Benjamin Murphy

He went away as he had lived nobly careless of himself and thinking only of the things he had undertaken to do?

 B^1 thought, by action and by self-discipline, he trained a body and mind given by a pure inheritance into a strong physique, an acute brain and a dominat ing personality

With unsatisfied industry he acquired the knowledge of his art and made his mind a possessor of the recorded deeds of his confrères of the world

He learned surgery serving with indefatigable energy the needs of helpless humanity and taking counsel of his fellow workers in every held old and new in which his profession was practiced.

He had a creative mind, trained to investigate facts, and suspicious of traditions with a courage to bring forth the new a judicial mind that judged so correctly the value of the new his genius brought forth that the things he wrought were recognized by science as enduring principles of surgery

He imparted to others his knowledge from a great storehouse by an irresistible enthusiasm, begotten by his appreciation of truth in a way that appealed to the mind, the conscience and the responsibility of his hearer and that made him the impelling teacher of his time.

His experiments were made in the laboratory in the dead house and in the animal operating room. He thus proved theories by facts but never at the expense of those he served.

The impelling text of his life—in experiments in writing in the practice of his art, and in his burning utterances as a teacher—was. Have appearment in your mind the welfare of the individual who entrusts his life to your care

He worked and pleaded for higher standards. He was democratic in his methods. He condemned complacent entrenched interests as a bar to progress. His life was a protest against ignorance and pretense He believed that most things worth while came from those not bound by tradition

He encouraged the beginner and listened to the obscure.

He labored with more and more concentration of effort, as the wonders and possibilities of his task were revealed, trusting his strong body inured by abste miousness and continued work to perform the almost superhuman task imposed upon it, and then the body broke and his life in the fullness of its power rus sacrificed. Greater love hath no man than this, that a man lay down his life for his fittends."

He loved God and expressed this love in his work for men and little children was the devoted father the beloved husband the staunch friend, and the inspirer of all who came within his influence.

He was the human man developing through many years of self-discipline indefatigable work, untold sacrifice and desire of highest service into the super man—the high priest of the most exacting profession.

THE EXTENDED OPERATION FOR CARCINOMA OF THE UTERUS

BY RLUBEN PETERSON M.D. FACS. ANY ARBUR MICHIGAN Professor of Obst. trick and Gynecology. University of Michigan

OUR years ago at the Baltimore meeting of this Society it was my privilege to take part in the sym posium on utering cancer. In that naper I said that while I believed in the radical abdominal operation greater experience had not made me any more consident that its primary or ultimate results would be tayorable to the next patient operated upon had no reason to change this opinion during the past four years Unfortunately added experience has strengthened my belief that the extended operation for cancer of the uterus is an exceedingly dangerous operation al ways attended by a high primary mortality and that it is no operation for inexperienced hands However it must be continually kept in mind that in spite of these defects today it is the only method unless it be the extended vaginal method which holds out to the patient with carcinoma of the uterus a reasonable hope of complete cure. I make this state ment in advance of what will be revealed by the other essayasts as to the results of radium or other methods of treatment. No one will be more glad to discard the radical abdominal method than will I if I can be shown that more patients can be ultimately cured by less dangerous methods

To arrive at any just conclusions regarding the radical operation it is absolutely necessary that the primary and ultimate results be considered together. Every one who has performed the operation realizes how easy it is to dodge the issue and perform what Clark has well called makeshift operations What is easier than to avoid going beyond a mass in one or the other broad ligament in which the ureter is embedded and tying the uterine artery close to the uterus as in the ordinary panhysterectomy? This choosing the easiest way may save the operator a primary death but it just as surely dooms the natient to a continuance of the disease and ultimate death as did the old vaginal hysterec Such an operation is not an extended operation for cancer of the uterus and should not be classified as such. If it be not ex cluded it will show in the final summing up for if the putients be kept track of they will be found to have died of so-called recurrences which in reality were no recurrences at all since the disease was not removed.

I would not be understood as asserting that an operator has not a perfect right to dodge the issue and save his patient primarily when he feels that a prolongation of the operation means but one thing—death However I do insist that such operations should not be classed among the extended operations for carcinoma of the uterus for if so included they give a false conception of the primary mortality in fact it is not enough to state that such and such operations were radical. If they be radical it will be demonstrated in the ultimate results — the number of patients surviving live years or more. If these results be favorable then and only then will we

be convinced that the operations were indeed leal har

Looked at in another way the burden of proof is upon the radical abdominal operator to show if his ultimate results are poor why he chose the abdominal in preference to the safer vaginal route as a palliative procedure, because it is a polliative method if it cannot be shown that quite a percentage of patients are alive and well after five years. We may or may not know at the completion of a cer tain radical operation whether it has accomplished its purpose. If macroscopic cancer ous areas have been left behind it should be stated in any classification of radical operations for cancer of the uterus that in so many cases the operations were performed while in other cases, although the radical operation was attempted, it had to be abandoned on account of an extension of the disease not

realized when the operation was begun. It is different with microscopic areas of Here it is perfectly justifiable for Cancer the operator to conclude that he has perform ed the radical operation, if the principles of the technique such as ligation of the uterine arteries external to the ureters and removal of a long cuff of vaginal tissue below the cer vical cancer be carried out. In reality ex cluding implantation metastases, an avoidable error of technique, every recurrence after a radical abdominal operation for cancer of the uterus, is evidence that the operator did not accomplish his purpose although he may have been justified in thinking at the time of the operation that he had.

PRIMARY RESULTS As in the former paper I shall still include cases of cancer of the fundus with those of the cervix for both classes of cases have been subjected to the radical abdominal operation. However in order that the operative results may be compared with others, the primary and end results of carcinoma of the fundus and of the cervix have been considered sepa Since the 1012 meeting I have not employed the extended operation upon a single case of carcinoma of the fundus but have depended upon the ordinary panhyster ectomy Since 1012 there have been 14

cases of ordinary hysterectomy for carcinoma of the fundus with two primary deaths or a primary mortality of 14 per cent. There have been two recurrences.

This is a worse showing than in the former report where there were it radical operations for carcanoma of the fundus with one opera tive death or a primary mortality of o per cent, and only one recurrence in the remaining to cases. It onfirms the position of Welbel who bases his conclusions upon 67 cases of carcinoma of the fundus from Wertheim clinic. These cases were operated upon by different methods radical abdominal simple abdominal panhysterectomies, supravaginal amputations and vaginal hysterectomies. While the radical abdominal method was attended by the highest primary mortality it also showed the highest percentage of ultimate recoveries, not withstanding the fact that this method was employed in only the most advanced cases. In 31 cases the regional lymph glands were found to be involved five times or in 16 per cent.

The only recurrence in 10 cases of cancer of the fundus surviving the radical operation reported in my last series occurred in a pa tient where remonal lymph-glands showed carcinoma. Just because our results are better in carcinoma of the fundus after or dinary panhysterectomy should not blind us to the fact that only by the very radical opera tion can the individual patient be given the best chance of a non-recurrence. There has been but a single recurrence in 10 patients surviving the radical abdominal operation for cancer of the fundus, although these pa tients are all beyond the five year limit. Hereafter I shall perform the radical opera

tion upon all operable cancers of the fundus I had reason to think that greater experi ence with the operation under discussion carrying with it necessarily a reduction in the time required to complete the operative procedure would lower the primary mortality in my hands. This expectation was further justified by my results, since there were only 4 deaths in the last 17 cases in the last series or a mortality of 108 per cent. But my hopes were doomed to disappointment since the mortality has been increased from

Total

22 5 per cent to 25.4 per cent there being

It is rather a thankless task to attempt to explain these latest deaths three of which resulted from shock and two from peritonitis The same technique was employed as with the previous cases but with far worse results I had thought it possible to judge with a fair degree of precision whether the cancerous process had advanced beyond the point where it was fairly safe to attempt the radical removal of the uterus especially if the final decision was reserved until after the abdomen was opened But I judged incorrectly in these cases since the patients died of shock the result of prolongation of the operation for a time sufficient to overcome the difficulties met with The two patients dving from pentonitis should have been saved but were not in spite of all precautions to avoid sepsis

It must be constantly borne in mind that every case of cancer of the uterus must be studied as an individual problem, so far as surgical treatment is concerned. First of all is the disease so far advanced as to preclude any hope that the patient can be cured by radical operation? Long ago it was determined that while much could be learned of the extent of the disease through careful vaginal and rectal palpation, the hald decision had to be made after the abdomen was opened. Only in this way is it possible to determine definitely the nature of induration to the sides of the uterus, whether due to cancer or to pelvic inflammation.

If the parametria be involved by cancer well outside of the uterus it must be decided from the extent of the involvement and the other factors in the case whether to attempt the removal of the carcinoma radically or employ some palliative procedure other factors in the case are the age of the patient not in years always but the actual age as revealed by the condition of the kidneys the heart and the blood vessels. Cancer pa tients do not stand prolonged operations well especially is this true when the uterus is the seat of the cancer This is easily de monstrated when such patients are compared with women of the same age who have had to undergo prolonged operations for other con

ditions in other words a patient with cancer of the utruis is a poor risk at best. Where the kidnevs and vascular system are impaired it may be folly to subject her to such a serious operation because of the slight chance of her primary recovery. It may be far better for the patient to prolong her life as much as possible by palliative measures.

Using our best judgment we may and do make mistakes and attempt the impossible with the result that the patient does not recover primarily. But it is the height of folly in my opinion to speak continually as if the entire question of primary mortality after the radical operation for carcinoma of the uterus depended solely upon the extent of the disease. As a matter of fact that is only one of the factors in the problem the others being nearly if not just as important.

The responsibility of what the patient will decide rests after all with the surgeon victim of cancer of the uterus above every thing else wants to be cured, not only on manly but so that there will be no return of She may be willing to take a great risk if there be a fair chance of being cured but not one woman in fifty but will choose palliative measures and the prolonga tion of life rather than an almost hopeless operation so far as primary results are con cerned It is hardly fair for the surgeon to justify his course of taking large chances with the life of an individual cancer-of the uterus patient by saying that inasmuch as without an operation she is doomed to a horrible death consequently any operative procedure is justifiable. By so reasoning

he is not respecting the rights of the patient whose wishes not the surgeon s, should be paramount.

OPERABILITY

I am in no position to speak regarding operability of the cancer cases seen by me since May 1912 since I have been trying out the various methods of cauterization and have not used the radical operation for cancer of the fundus when it could have been employed. During the post four years I have seen in my university and private clinics 124 cases of cancer of the uterus, 107 cases of cancer of the fundus (Table III).

Unquestionably some of the cancer of the carvix cases could have been subjected to the radical operation, just how many I am unable to say but I was anxious to give the cautery treatment a fair trial not only in the so-called inoperable cases, far advanced cases, but those in the doubtful class as regards choice of operation. Again, 31 patients were so far advanced that pothing could be done or else they refused operation.

I was not fortunate in my selection of cases for the radical operation as shown by my results, and the discouragement that followed undoubtedly influenced me in the choice of cautery methods. However my experience with the cautery has not convunced me that it is in the allightest degree curative. On the contrary I believe that the method must be reserved for those cases of cancer of the uterus where palliative measures only are indicated or where it may be serviceable in preparing a cancerous cervix for radical removal.

I have already spoken of my experience with panhysterectomy for fundus carcinoma Tasts IV—Eo-Lecults of the Redical Abdominal Operation—5 Cases of Casce of the Cert's and Fundas operated upon thrust five years ago Number of cases 5 Primitary deaths 4.1 Number of recurrency 41 Number of recurrency 1.2

60 of

and my determination to employ the radical operation in the future for this class of cases.

With the exception of these comparatively few cases where the radical operation might have been or was employed, the very large proportion of the cases of uterine cancer were inoperable from the standpoint of a possible cure. They were far advanced cases even more if I am any judge than the previous 125 cases which came under my observation. This is not very encouraging so far as the results of our campaign against cancer are concerned, but it furnishes convincing proof of the need of such a propaganda.

END-RESULTS

I am able at this time to report the end results of 41 cases of cancer of the cervix and fundar since the patients have all been operated upon five years. I am aware that percentages based upon such a small number of cases have only a relative value when compared with percentages of other operations based upon a large number of cases. As a matter of fact however we must employ the percentage method, if we are to compare results both large and small. Still it is best to keep in mind that percentages favorable or unfavorable, in a small series of cases do not tell the whole story.

In Table IV been have recorded the end tensils in 5x cases of cancer of the cervix and tundus combined, since the radical operation was performed for both classes of cancer Naturally the end results will be better than when cancer of the cervix is considered alone, since there is less tendency for carcinoma situated in the fundus to recur I might again emphasize the point that this is true if the radical operation has been employed, the

tion (Wertheim s formula)	62	%۰

reverse being the case if ordinary panhystered tomy has been done

In the 41 patients surviving the radical operation there were 12 recurrences two died of intercurrent diseases one tuberculosis and the other heart disease There were 27 natients alive and well five years or more after the radical abdominal operation.

In order that there be no misunderstanding regarding the method of arriving at end re sults in this and the other tables it may be well to state that every patient was located and her condition ascertained for this report. In other words just because a patient with cancer of the uterus operated upon radically had passed the five year limit at the last report four years ago it was not assumed she was well today. Her condition was ascertained by a letter from the patient herself or from her physician. Fortunately I am in a position to keep track of these cancer cases and have been able to secure the post-operative history of each patient.

Wertheim's rules for working out the statistics of the end results for cancer patients subjected to the radical operation have been followed in the tables because they are the simplest. All patients who die from intercurrent disease or who are lost track of must be subtracted from the total number of operations to ascertain the percentage of permanent cures in all cases operated upon To obtain the percentage of permanent cures of those surviving the operation the number of pa tients living five years or more after the operation must be divided by those surviving the primary operations after deducting those dying of intercurrent diseases and the number lost track of

TABLE VI - End-Results of the Radical Abdommal Operation for Cancer of the Fundua 11 Casca operated

	Percentage of primary mortal ty		I
	Number of patients with recurrences	1	
	Percentage of recurrences	0	ь
- 3	Number of patients at re and well at least five		
	years after operation	9	

The end results as shown in Table IV are surprisingly good and very encouraging Five years or more after the operations 56 2 per cent of patients operated upon for cancer of the cervix and fundus are permanently cured while 60 2 per cent of those surviving the operations are well with no recurrence

In order to forestall objections that the results were due to the inclusion of fundus with cancer of the cervix cases the latter to the number of 40 the total number operated upon five years or more ago have been ar ranged in Table V The greatest interest centers around the number of patients alive and well after five years (18) Thus 47 3 per cent of the total number of patients with cancer of the cervix subjected to the radical abdominal method remain cured after five or more years while 620 per cent of those surviving the operation remain cured

But better than percentages better than anything else is the knowledge that 18 women out of 40 subjected to the radical operation for cancer of the cervix may be pronounced cured since they have passed the five year period without a recurrence compensates in part for a high primary mor tality since very few if any of these women would be alive today had other methods of cure been attempted

There have been no further recurrences in the II patients with cancer of the fundus mentioned in the last report, Table VI these one died from the operation and one from a recurrence one year after the operation The remaining o patients are alive and well from five to twelve years after the operations It has been considered inadvisable to figure the percentage of cures in such a small series of cases

The time clapsed since the radical operations has been recorded in Table VII tients have gone five years five patients six

years seven patients seven years, three patients eight years, two nine vests, two twelve years, and one patient eleven and threten years respectively. While it is impossible to state positively there will be no further recurrences in this sense of patients who have passed the five year limit, we have every reason to believe that such will be the case in most instances. However it is interesting to note that one of the recurrences and deaths occurred in a patient who had been apparently free from the disease for five and a half years after the radical operation for cancer of the cervits.

It may be stated that the patient mentioned in the last report as having had a recurrence in the vagnal cleatrix five months after the operation with no recurrence for two years subsequently died of the disease.

SUMPLARY AND CONCLUSIONS

- r Further experience with the radical abdominal operation for cancer of the uterus confirms the belief that it is an exceedingly dangerous procedure and will always be at tended by a high primary mortality
- Even if the percentage of operability of cases of cancer of the uterus markedly increases in this country and elsewhere there will always be border line cases attended by a high primary mortality
- This is true because it is not always possible even with the greatest care in examination of the patient prior to operation to estimate the extent of the disease.

- 4 Errors in judgment mean death from shock if the disease be too far advanced or failure to complete the radical removal of the cancerous utents.
- 5 However in spite of a high primary mortality it is the only procedure with the possible exception of the extended vaginal operation which holds out any reasonable
- promise of a permanent cure
 6 Primary and end results of the radical
 operation for cancer of the uterus must be
 considered together in order to judge of the
- good accomplished in a given series of cases.

 7 Unless the operations be radical the end results will be poor and if they be radical.
- end results will be poor and if they be radical
 the primary mortality must be high.

 8 If the end-results be poor the burden of
- proof is upon the radical shdominal operator to show why he did not choose a much safer pulliative procedure 9. Since 1912 experience with 14 ordinary
- Since 1912 experience with 14 ordinary panhysterectomies for cancer of the fundus shows worse primary and end results than in 11 cases previously reported where radical removal was performed.
- To This showing and the results following removal of carcinoma of the fundus by various methods in the Werthelm clinic as reported by Wesle lead to the conclusion that, because cardinoma of the fundus is more easily cured than when the cervix is involved, we are not justified in thinking it can be treated any less radically than carcinoma of the cervix.
- 11 The primary mortality in 59 cases of cancer of the cervix and fundus treated by the radical abdominal operation was 25.4 per cent.
- 12 The extent of the involvement in cancer of the uterus can only be determined definitely after the abdomen has been opened. If the parametria are not too much involved and the conduiton of the patients kidneys heart, and blood-vessels warrant a prolonged and depressing operation it is justifiable to attempt the radical operation.

 13 Dunng the past four years 124 cases
- of cancer of the uterus have been seen in the university and private clinics. The disease was so far advanced in 36 cases that operation was refused or nothing was done. The cautery

method was tried in 58 cases and proved valueless except as a palliative procedure

- 1.4 In spite of attempts to educate the public regarding cancer the cases of cancer of the uterus seen during the past four years were more advanced than has formerly been the case
- The end results in 51 patients operated upon five or more years ago were most gratifying combining fundus and cervix cases 27 of the 51 patients were alive and well after the years or 56 2 per cent of all cases operated upon while 69 2 per cent ot all those sur viving the operations were alive after hie years.
- 16 Of 40 cases of cancer of the cervix operated upon five years or more ago 18 of those surviving the operation are alive and well today. Thus 47 3 per cent of the total

number remain cured after five years while 62 per cent of those surviving the operation remain cured

- 1. These percentages were obtained by Wertheim's formula where patient dying of intercurrent disease or tho clost track of are subtracted from the total number of operative cases or from the number surviving
- 18 The length of time elapsed since the operations upon the 18 patients who are alive and well vary from five up to thirteen years. There is every reason to think these patients are permanently cured although one patient did have a recurrence and died between five and six years after the radical operation.

19 In spite of the high primary mortality the end results in those urriving the operation encourage us to continue with the procedure in urtable cases

Y-RAY TREATMENT OF UTERINE HEMORRHAGE

By ROBERT T FRANK AM MD New York
Associate Gyperologist, Mt Smal Hospital

INTRODUCTORY

THE \ ray has been employed in gyne cology for a sufficient length of time to allow the profession to form an accurate idea of the ments and dements of this method of treatment. Nevertheless the conclusions arrived at vary greatly Some authors particularly those of the Frei burg school and many roentgen therapeutists laud the \ ray highly others especially certain gynecologists view the entire question of \ ray therapy with suspicion and are in clined to class the method with the numerous transitory fads so common in contemporary medicine

The present paper aims to defend \(\) ray therapy from its friends Properly employed in properly selected cases the treat ment is invaluable and indispensable in gyne cology used promiscuously by the unimitated roentgenization is as dangerous as the sur geon's scalpel in the hands of the ignorant and the meddle-some

The writer has used the \ ray for a num ber of years. He has never given the exposures himself but has always referred the patients to the same roentgenologist selection of cases the general directions (i.e. the effect to be attained such as the toning down of bleeding amenorrhoea etc) the control of physical findings have remained in the writer's hands while technical questions have been left entirely to the judgment of the I ray specialist. No attempt to discuss the minutize of technique will be made in this Such information is readily accessible (1) Burns or other serious disturbances are practically unknown today if treatment is entrusted to competent hands

MODUS OPERANDI OF THE RAYS

The X rays affect uterine hæmorrhage in directly by their influence upon the ovaries (2) there is also a certain amount of evidence that uterine fibromyomata are influenced directly (3)

Ripe and partly ripening folicles are very susceptible to the rays. Primordial folicles on the other hand are extremely resistant even to measive and prolonged exposure, the ovaries of young women proving more resistant than those of older females. Whether this increased resistance is due purely to the greater number of primordial follicles in the young is not known.

As the menstrual function is dependent upon ovulation and the subsequent development of the corpus luteum (4) such uterine harmorrhages as result from normal or abnormal ovarian influences are necessarily affected by the inhibition of follicle mpening and ovulation. If all ova are de stroyed, permanent amenorrhoen results if all noe and ripening follicles are killed menstruction ceases, until some primordial follicles have had time to meen and to rupture. Moreover considerable clinical evidence obtains that certain qualitative changes arise from roentrenization and persist after cesaution of treatment, such as permanent diminution of menstrual bleeding The physiological changes at the bases of this nhenomenon are unknown

Certain observation showing increase of connective tissue in fibromyomata which were subjected to raying have been interpreted as direct \text{\text{ray effects (lse csl)}}\text{\text{Outre possibly however the fibrosis is an involution effect due to the withdrawal of ovarian atimuli from the tumors, comparable, though not identical, with the shrinkage of fibrodis usually noted at the physiological menopause

TECHNICAL

Fractional treatment implies exposure to the rays for 4 to 6 minutes of one or more large fields in the lower abdomen two to three times weekly over long periods of time. Suggraduated dosage, though slow of effect, usually permits of accurate control of the degree of influence exerted upon the ovaries. It is therefore, especially recommended for cases where reduction of bleeding and not amenor though the desired.

Intensive treatment according to the improved Freiburg technique permits of the use of enormous doses at each sitting (small multiple fields filtration cross fire and lately also the Coolidge tube) By this means amenorrhora may be achieved within a short period of treatment (o to 18 weeks) This form of treatment is applicable to cases in which profuse bleeding must be controlled within a short period of time. Graduated effects are less readily obtained

It is at times indicated to give one or two intensive treatments, to obtain control of the bleeding and then to continue with fractional doses in order not to produce amenorrhosa. An experienced technician can thus produce the desired effects almost at will.

APPLICABILITY

Y ray therapy is applicable in

1 Functional menorrhagia and metror

2 Functional menorrhagia and metror rhagia during sexual maturity

3 Functional menorrhagia and metror rhagia preceding the dimacterium

4 Menorrhagia and metrorrhagia due to fibromyomata.

Idolescent kæmorrkages Prolonged and irregular higmorrhages between the ages of 13 and 18 years are not uncommon. The majority of cases respond to general tonic treatment, uterine styptics (errot, styptol) and hygienic measures. A small number require one or more curettages. A still smaller number in whom the preceding measures fail to cure are relieved by scrum injections calcium chloride by mouth or rectum, or transfusion. The few remaining cases, usually quite desperate because of their extreme anamus and debility after all measures have been tried in vain, are saved from hysterectomy or cophorectomy by \ ray treatment. One or two intensive treatments are followed by fractional exposures until complete amenorrhors is obtained. This effect is usually not attained for several months during which the bleeding occurs less and less frequently and in diminishing quantitles. If vasomotor symptoms (flushes) develop the exposures should at once be diminished, as the dosage has been sufficient to produce amenorrhoes within a short time.

The amenorrhoea may persist for 8 to 12

months then scant and irregular (every 5 to 6 months) period appear hnally normal menstruation is re-established. Permanent amenorrhea is almost impossible to obtain in very young women.

Functional menorrhagia and metror rhagia during sexual maturity Occasionally cases are encountered in which purely functional hæmorrhages necessitate interference The patients usually are in the early thirties and have had one or more children bleeding may take the form of either menor rhagia or metrorrhagia or both Inflamma tion can be excluded both by the hi tory (absence of venereal intection normal puer periums etc) and by the physical findings Usually the sole change noted is a moderate symmetrical increase in size of the entire uterus Repeated curettages either produce only temporary palliation or are of no avail The curettings regularly show endometrial hyperplasia or cy ticendometrial changes Formerly such cases after palliative measures had failed were treated by atmocausis or hysterectomy. Some of these nationts desire more off pring

When the condition 1 clear—ie absence of inflammatory learns curetting showing absence of carcinoma—\text{Nav} treatment is applicable. It no more children are wanted amenorrhoza may be induced otherwise the bleeding should be toned down by fractional dosage the more advanced the age of the patient the les exposures are needed. When the periods occur only at to_t months intervals and are canty it is well to temporarily stop treatment in order not to run the risk of producing the menopause. Such patients may later conceive and bear healthy children.

3 Functional preclimateric menorrhagia and metrorrhagia. In these cases carcinoma must always be excluded by one or more curettages (muro copical control). The cu rettings ordinarily resemble those obtained in Class 2. Unless the adnexal regions are free \(\nagle \text{raying is also contra indicated.}\) Many of the cases clinically fall into the group of we-called into its uten invopathies meeting etc.

Other thing being equal the patient should

be given the choice between operation and \(\) ray. In cases in which vaginal by terectomy promises to prove technically cay operation hould be preferred on the other hand in obesc emphysimatou patient, or those appearing to be poor operative \(n \) k roentgen treatment is to be recommended as less dangerous than operation

A few intensive treatment regularly produce permanent amenorrheea. If thi out come is not obtained a mistake in diagno is has been made (carcinoma pedunculated submucous fibroid)

4 Menorthagia and metrorthagia due to nbromy omata. This class of cases has given rie to the largest amount of this us ion Kroenig and Gauss (6) claimed 100 per cent cures where the method was used and an applicability of 85 per cent. The writer on the other hand finds an applicability of only 5 per cent in hi material (7). Between these widely divergent views all manner of opinions are noted.

To form a correct opinion a number of factors must be taken into consideration. The discovery of a symptomies inbroid per se does not indicate any interference. In the writer's experience only 45 per cent of in broids require treatment especially if the patient is not informed of the presence of a tumor. Some member of the family may be made aware of the condition in order to safeguard the physician Luless inbroids produce memorrhagina and metrorrhagina.

safeguard the physician Unless abroids produce menorrhagia and metrorrhagia pressure symptoms or enlargement of the abdomen their presence is rarely noted and operation not considered.

Bleeding is the symptom most often complained of and most readily relieved by

plained of and mo t readily relieved by raving Betore \(\text{ray} \) retained an be considered carcinoma must be excluded by exploratory curettage. The absence of can cer can be demonstrated only if the entire endometrial cavity 1 accessible to the curette Uten which contain tortuous cavities (submucous fibroids) ought therefore not be rayed.

Where pressure symptoms are severe or where large tumors are noted the writer excludes the use of the rays becau e several months of treatment mu t clapse before con -46

siderable reduction in size of the mass and consequent relief can be looked for

Kroenig and Gauss consider the following conditions as contra indicating \(\) my treat ment

Pedunculated submucous fibroid partly
extruded from the cervix.

Gangrenous or suppurating fibroids.
 Combination of fibroid and endometrial

carcinoma.

4. Fibroids in which rapid growth, profuse metrorrhagin, and unsuccessful roenteen

treatment makes the fear of sarcomatous degeneration likely 5 Fibroids causing acute incarceration of

the bladder

Besides this they rarely recommend radio-

herapy for patients below the age of 35 years as permanent amenoration is difficult to obtain.

These contra indications are not sufficiently rigid. Abdominal diagnosis, including gyne-cological diagnosis, is notionally uncertain Surprises are constantly encountered. Even the experienced clinician will occasionally

ally up" on an apparently simple diagnosis, mistaking, for instance a cyst for a fibroid. In order to protect the patient, it is necessary to exclude all doubtful and complicated cases. What constitutes a doubtful or a complicated case remains a matter for the judgment and experience of the gynecologist to decide. The writer in a series of 419 unselected cases, which were admitted for operation to Dr. Brettauer's service at Mt. Sinai Hospital, found 140 complicated cases (35 per cent) as tho Table I will show

Of the 140 cases at least 74 (18 5 per cent) presented conditions absolutely contra indicating raying Many of these conditions were not and could never be diagnosticated before operation.

Absolute contro indication to \ ray treat ments in the writer's opinion is present, if carcinoms or sarcoma are found or suspected if ovarian cysts or tumors are felt, if the uterino tumor is rapidly growing if the tumor is large (size of a 5 to 6 months pregnancy) if the palphatory findings are doubtful (suspicions

of adnexal trouble, of rectal or sigmoid tumor of adhesions, etc) TABLE I

Common common access of the contract of the co

Pedunculated or degenerating tumors, when recognizable are also contra indications. Urgent symptoms will necessarily preclude the use of the rays.

In clear cases of uncomplicated fibromyomata not excessive in size but causing symptoms, the question of raying cross operation may be considered. The decision rests with the patient, who should be enlightened in regard to the risk of operation (mortality o 5 to 2 per cent) on the one hand, contrasted with the duration and expense of \ ray treatment on the other.

SOCIAL CONSIDERATIONS

A ray treatment can be given to the lim pecunious only in well equipped and well en dowed institutions. In addition to the initial expense of the installation the operator's time the electricity consumed, and the re placement of tubes etc produce a formidable expense account. Fractional expensers (4 to 6 minutes) cost approximately \$3 co each to cover expenses and may have to be con tinued 2 to 3 times a week for many months. Intensive exposure, sufficient to produce amenorrhora and shrinkage of a fibroid to a

In one spectrose, y partents find. In 4 of them the pays could not have been send moreone of extent and payellones of every formal and programmy with bisoclaw necrotic fabrul a structure from courts, sopraslizant incommunity hadder women i reaction. woman over 35 years of age will cost from one hundred to three hundred dollars at a minimim

INDICATIONS

Taking into consideration the absolute contra indications the danger of operation the expense and time involved the writer believes that about 5 per cent of fibroids (i.e. 10 per cent of those requiring interference) should be treated with the \ ray These indications are met in uncomplicated cases in which (1) operation is declined in which (2) operation is contra indicated be cause of extreme nervousness or psychical un rest, in which (3) operation is inadvisable because of serious heart disease renal or pulmonary lesions

SUMMARY

- The roentgen ray produces amenorthæa by destroying the ovarian follicular apparatus or oligorrhoea by partial destruction of follicles. The resulting menopause symptoms correspond in character and degree to those of the post-operative menopause
- The choice hes between two methods of application (a) the fractional weak requiring prolonged use but readily controllable (b) the intensive massive more rapidly producing amenorrhoea
- 3 Obstinate cases of harmorrhage in adolescents can be cured. Only such cases as have resisted all other forms of therapy should be selected
- Functional hæmorrhages during sexual maturity if conditions are unmistakable and curettage shows absence of carcinoma. may be relieved by producing oligorrhoea (with the possibility of subsequent pregnancy) or definitely cured by inducing the artificial menopause.

- 5 Prechmacteric functional hæmorrhages are readily cured by the production of the menopause. At this age malignancy must be even more carefully guarded against
 - 6 Uterine fibroids may be slowly reduced. by X ray treatment. All complicated cases should be excluded as otherwise serious or fatal mistakes may occur In properly selected cases (5 to 10 per cent) the choice between operation and roentgen therapy may be left to the patient. In patients with serious heart lesions nephritis or pulmonary trouble or in the hyperneurotic preference should be given to the \ rays

CONCLUSIONS

A ray in gynecology has proved an invalu able addition to our armamentarium ables the gynecologist to exert graded effects upon the ovary and thus control the men strual cycle in degrees varying from slight in hibition to permanent destruction of function. It also causes fibroid tumors to diminish in size or to disappear

The main danger to be apprehended in I ray treatment is their application by error to malignant tumors Such danger is mini mized by excluding cases which present doubtful or complicated findings the treatment must always be controlled by the trained gynecologist because diagnostic accuracy is far more essential than if opera tive measures are contemplated

PRECANCEROUS CHANGES IN THE UTERUS

By WILLIAM S. STONE, M.D. NEW YO

THE failure of scientific medicine to discover either a cause or a cure for cancer does not deny an assurance of a promising field in a more definite investigation of the local physiological and pathological changes which relate to the inception of the disease in individual organs.

Numerous conditions are recognized clin ically as preceding or associated with cancer of the uterus in a variable percentage of cases. Trauma of the cervix during parturition re sulting in a variable amount of ectropion is generally regarded as an important factor in the etiology of cancer of the uterme neck, but its histogenetic algorificance - whether related to the presence of scar tissue, to regenerative hypertrophy or in furnishing a larger field for atypical strife between two kinds of epithelium - is far from established. Chronic inflammatory diseases are becoming more definitely recognized as antecedents of neoplastic growth in the uterus, as well as in the breast and other organs.

Polese (1) for example, states that an endocervicitis preceded cancer of the cervix in 34 of his 48 cases and we find in the records of numerous observers how often such changes are related to the history of gonorrhom less often to that of tuberculous. Syphills is more definitely related to the inception of a cancerous disease in some regions of the body than any other common disease. the uterus its relation is less well defined, but with our present resources in diagnosis a promising field for pathological research appears to be furnished in a closer study of those lesions designated as leucoplacia. Ewing (2) states that the cervical erosion is the most definitely established lesson known to precede cervical cancer and for corpus carcinoma, he says, the chief definite etiological factor is the association with myoma. Evidence of this frequent association of myoma with cancer of the uterus is furnished by numerous writers Taussig (3) states that in a personal communication from the Mayo Clinic be learned that

myomata were present in 10 out of 40 cases of cancer of the corpus uten in that clinic

The observation of such causal relations however important they may be in the study of the occurrence of uterine cancer does not include its formal histogenessa the study of which becomes necessary in order to define the term increancerous.

Clinicians are generally agreed that there are no pathognomonic symptoms of uterine cancer until the tumor growth has become well established and usually not until its destructive capacity is grossly manifested Atypical bleeding or discharge combined with other symptoms and a careful physical examination can only create a weak or strong suspicion of its early existence without the aid of a competent histological examination from which it is universally expected that a positive confirmation or denial of the clinical suspicions will be made Failure to receive a positive diagnosis often creates in the mind of the clinician a suspicion of the incompetency of the pathologist or in the mind of the pathologist that he has not been furnished with the proper material. Each of these conditions may maintain but an analysis of the histological criteria upon which a positive diagnosis of a fully established cancerous growth is made shows that the pathologist, like the chnician is ordinarily not prepared to make such a diagnosus until some amount of destructive capacity is histologically man ifested In other words, cancer is an evolutionary process requiring time to show its actively destructive purpose Ewing (2) says. It is not true that a pathological con dition must be either cancer or not cancer It may be neither the one nor the other may be in the process of becoming cancer Using this author's analysis of the histological criteria in the diagnosis of cancer we have

(1) Cellular overgrowth passing beyond that observed in other processes affecting the same tissue (2) atypical qualities of the cells metaplazia, anaplazia (3) loss of

Read before the American Gysecological Society Washington, May 4, 416.

polarity (4) heterotopia (5) desmoplastic properties (6) local invasive properties (7) metastases Before there is an appre ciable amount of heterotopia or invasive features however innumerable combinations of criteria may be seen each varying in quant ity and quality. In some cases the amount of proliferation will make a striking feature in others the atypical quality of the cells their size irregular shape peculiar staining qualities especially the larger size and hyperchromatism of their nuclei or their loss of polarity - will present such pictures that one feels reasonably certain that a malignant To many growth is in a developing stage of such areas the term precancerous seems to be appropriately applied

In the literature of uterine cancer we find much to support the idea that the evolution of a malignant growth can be observed from its beginning in definitely benign lesions to a stage in which it becomes a fully developed neoplasm Schottlaender and Kermauner (4) in their extensive monograph express the evolutionary character of cancer in the use of the terms immature moderately mature and fully mature according to the number and kind of morphological features that they present without regard to their histological type size or age. Contrary to the opinion of the majority of pathologists they believe that although there is no specific criterion by which the earliest beginnings of cancer-cells can be recognized it is possible to recognize an immature stage of cancer before its destructive growth is shown especially in the squamous cell form most of which appear in this stage. To those cases in which the morphology appears doubtful they use the term precancerous other writers are not so frank in the use of this term there is much evidence in their discussion of atypical changes of benign le sions in the uterus and their relation to the development of malignant growths to justify its application to a definite variety of inter mediary changes

Metaplasia The transformation of cylindrical epithelium into the stratified variety has been produced experimentally in the stomach of lower animals by Fuetterer (5)

and Possner (6) and metapla ia of epithchum in the gall bladder stomach urethra and other organs has become established as a definite factor in the development of squamous-cell carcinoma in these organs uterus offers an especially fertile field for the study of the significance of this change in the evolution of malignant neoplasms certain amount of unithelial change and proliferation is shown by Klein (7) Mueller (8) and others to occur as a result of the physiological functions of menstruction and pregnancy and the factor of atrophic changes of the surface epithelium after the climacteric in the production of epidermization is discussed by Moericke (a) R. Meyer (10) in finding islands of stratified epithelium in the surface epithelium of the uterine body of a newborn infant and in subsequent observa tions has contributed much to the factor of developmental error Friedlaender (11) ob served small islands of stratified enithelium both on the surface and dipping in a few places into the glands of the lower segment of the uterine body of a child of five which he ascribed to hæmorrhagic iffusions and exfoliation of particles of mucosa during a severe scarlatinal nephritis. The potential frequency of metaplastic change in the uterine mucosa is discussed by Werth (12) in the regenerative changes following curettage trequency as presented by Zeller (13) in every form of chronic endometritis is questioned by subsequent writers but its occurrence in long existing chronic inflam mation due to gonorrhoea tuberculosis and perhaps to syphilis is amply attested by numerous observers — Gebhard (14) von Franque (15) Ruge (16) Hengge (17) Oeri (18) Kaufmann (19) Sitzenfrey (20) Schau enstein (21) Hitschmann (22) for an ex planation of this process in the uterus offers the view that under pathological conditions the uterine epithelium may acquire the old embryonic capacity of that of the mueller duct to form indifferently either cylindrical or stratified squamous epithelium in any part of its course and believes that, exclusive of polypi and other benign tumors its presence in the form of a true epidermization does not occur except as a mulignant process. As a

histological criterion in the diagnosis of neoplastic changes its importance is related to its diversity of form and extent in those lesions under discussion

Certical crosson The strongest argument against the histogenesis of carcinoma from this lesion has been the apparent infrequency which cancer has been observed clinically to follow such a common lexion. The best clinical record of such a sequence is that of Beckmann (23) who in a case, 37 years of age, that he had treated for an erosion over a period of five years finally saw a squamous cells carcinoma develop. In another 43 years of age, after two years duration of a lesion diagnosed as ectropion, an excusion was made one and one-half years after which a carcinoma appeared. Several factors sug gest themselves as contributing to the infrequency of such observations (1) The failure of the patient to consult a competent clinician before the tumor is well established (2) the length of time that such benign lesions probably exist before atypical changes begin preclude the continuous observation by a sungle clinician (1) the frequent cure of such leafons by minor surgical procedures (4) the orthodox conception of the pathol ogist that no intermediary stages can be recognized morphologically between be nion and neoplastic change. The evidence. bowever in pathological literature has be come sufficient to direct our attention to a closer study of the atypical changes which frequently occur in the course of healing of cervical erosions. Ruge and Velt (16) long ago expressed the opinion that erosions are not always a simple and unimportant process, and that an isolated erosion gland cannot always be differentiated from an isolated carcinoma gland without the surrounding tissues. Amann (24) refers to a number of cases in which the newly formed epithelium in a healing erosion spreads like a portio epithelioma. Winter (25) states that a true portio epithelioma not rarely forms from a healing erosion. Koblanck (16) can only express the differential character of a healing erosion and a portio carcinoma in the greater or less amount and regularity of enithelial metaplasia and the more or less atypical

qualities of the cells. Altien (27) has traced a carcinoma of the vaginal vault to a follicular erosion gland in a case of endocervicitis. Von Franque (15) in a case 43 years of age, found typical carcinomatous epithelium in the glands of a follicular erosion which he re garded as suspicious. Rubin (28) has recorded three cases of undoubted increient cancer arising in a definite proliferation of atymical enithelium on the surface and in the glands of healing erosions, in which the diagnosis was made (1) from indistinct definition of cell outline, especially in the deeper layers (2) from the irregular large. hyperchromatic nuclei occasionally lumped together (1) no definite stratification of the layers and lack of abgriment of the basal cells (4) marked nuclear granulation, as seen frequently in carcinoma in which born! fication has not appeared. Mitoses and hor nefication, he regards as variable qualities. Schauenstein (21) gives a comprehensive description of the evolutionary features of cancer of the cervix in a report of four cases. His first case presenting an atypical prolifera tion of enithelium cells in a circumscribed area of the portio and along the lower part of the cervical canal, differed quantitively from a healing erosion in the amount of cell prolligration along the surface and the extent to which the glands were filled with stratified epithelium and, qualitively in the atypical character of the cells, in their loss of polarity in the deeper layers and the presence of numerous atypical mitoses. The other three cases, which appear to be def initely established carcinomata, differed from the first case in the amount of their atypical qualities and in the distinct heterotopia and slight stroma invasion. No macroscopic growth was found in any of the cases but in the three fully established growths it extended superficially along the entire cervical canal in one to the lower part of the corpus mucosa in another and to the corpus and vaginal wall in the third the vaginal epithelium being preserved over the growth. The morphology of the cells in the first case differed alightly more from those seen in atypical healing crossons than it did from the other three cases the latter differing from

each other chiefly in the amount of definition of cell outline Under a high power the differentiation between the cells of the first and other cases he says could not be made Schottlaender and Kermauner (4) made a similar observation regarding the differential morphology of such cases In other words Schauenstein made the diagnosis of a def initely established cancer in three of his cases by a destructive action manifested by a distinct heterotopia and invasion of the glands not only by a direct proliferation through their mouths but also by bursting through their walls with which they came in contact He believes that the first case was becoming a similar growth and only needed time to show its destructive action K Ulesko-Stroganowa (20) in a report of three cases describes the histological features of developing carcinomata on the base of healing erosions but her drawings do not confirm the descriptions and the rapid regression of the processes that she was able to demonstrate by an examination of the uters which were removed four weeks later in two cases and of the cervix which was amoutated two weels later in the other makes it seem probable that in these cases there was only an exaggerated amount of cellular proliferation in the process of a healing erosion in two of the cases and a gonorrhoral infection in the other They show however the evolutionary char acter of the process Cullen (30) to whom we are much indebted for his analysis of the histological criteria in the diagnosis of uterine cancer shows pictures of sections in the neighborhood of fully established tumors which he regards if taken by themselves as suspicious 1 If no other evidence of growth existed how shall such changes be interpreted except as representing the developing stage of cancer?

Leucoplacia The potential elements in these lesions of the tongue to develop cancer has long been recognized. Wenr (31) 1875 was the first to describe leucoplacia of the female genitalia in the report of two cases occurring upon the vulva both of which developed cancer. Since then a few writers have described their occurrence on the vagina portio cervical and utenne canal which in

Pages 57 890, 203.

most instances after a long time have de veloped into cancer \on Franque (15) made the first clinical observation of leu coplacia of the portio developing into a car cinoma observing the case as beginning in an His second case observed over a period of six verifs finally became a carcinoma. Berkeley and Bonny (3) consider leucoplacia of the vulva as the first stage of cancer Sweeney (33) reports a case 3, years of age giving a history of syphilis and a positive Wassermann It was also associated with a gonorrhaal pyosalping to improvement followed the use of salvarsan and six months later a hysteractomy was done importance has been written regarding the etiology of these lesions in this region or their relation to syphilis except that in a few instances there has been a history of syphilis So few cases of uturine leucoplacia have been recorded that it must be considered clinically a rare disease. It has appeared in the cases so far reported on the portio in association with similar and usually more extensive areas upon the vaginal walls or extending along the cervical and utenne canal to the fundus. The lesson appears as yellowish white slightly elevated patches of different sizes discrete or joined to each other by narrow bridges The patches are adherent to the underlying tissue which bleeds if they are wiped away (von Franque Sweeney) It has been described in a more extensive and diffuse form under the name of psonasis or icthyosis by von Rosthorn (34) von Franque (15) Zeller (13) and others Its pathology as given by d Hotman de Villiers and Thérèse (35) Jayle and Bender (36) von Rosthorn (34) and von Franque (15) consists of a marked metaplasia and thickening of the horny layer with increase in the keratohyaline granules of the stratum granulosum (Sweeney 33) resulting in complete epidermization and often showing considerable epithelial down growth The more extensive growths which have existed a long time may present the picture of an adult acanthoma as for ex ample the case of von Rosthorn (34) which is so regarded by Hitschmann (22) and others This epidermization of the uterine mucosa relates specifically to the histogenesis of a

number of recorded cases of carcinoma, in which an extensive but superficial spread of the growth has occurred, covering a greater part of the mucosa of both the corous and cervir-von Pierung (37) Ruge and Veit (16) Benckiser (18) Hofmeier (10) Gebhard (14) Cellhorn (40) Kaufmann (10) Schauen stein (21) Some of these cases have shown acanthoma in the corpus and adenoacanthoma in the cervix, or focal areas of acanthoma in an adenocarcinomatous structure for which an explanation may be reasonably found in the pre-existence of leucoplacia. Pfan nenstiel (41) says every case of epidermiza tion is not suspicious, but it is a precancerous stage in the same way that glandular hyper trophy and hyperplasia is to adenoma and

adenocarcinoma. Uterine polyps Numerous writers have directed attention to the frequency of sufficiently atypical epithelial metaplasia and overvrowth in uterine polyni-klob (42) Billroth (43) Amann (24) Keitler (44) Winter (25) Kroemer (45) Bulius (46) Kuestner (47) Gessner (48)—to furnish evidence of their malignant tendency Oeri s (18) description and drawings of the changes in both the surface and gland epithelium justify his conclusion that, although a diagnosis of a fully established neoplasm can not be made, they contain the potential elements of a developing cancer. He also reviews the literature of amilar cases. J Williams (49) describes a mucous polyp in which the down growth of epithelium into the glands is atypical enough to create the impression of a developing malignant growth. Opits (50) directs attention to the frequency of epithelial metaphana over that part of the polyp projecting into the vagina in which he sees a base for the development of a malignant chance

Submucous fibrourowada The importance of these tumors in the development of car canona, especially if they become pedua nutritional changes they produce in the neighboring mucosa. We are indebted to Streaffrey (-o) for a comprehensive description of the changes which occurred in two cases. In the first instance, the histology

of the curettings in a case of necrotic submucous fibroid showed an immature epider misation and a slight papillary proliferation of the surface enithenum and mouths of the gland ducts. In one area the cells became more atypical and heterotopic suggesting at two points a beginning invasion of the underlying strooms from which he regarded the case as strongly suspicious of a malignant formation. The case remained well how ever during 4 /2 years of observation. the other case 50 years of age a submucous fibroid had been removed six years previously A curettage for bleeding and discharge re vealed an extensive metaplastic growth of surface epithelium and deep invasion of the gland ducts. Because of her age the presence of a necrotic polyp and other submucous myomata, a hysterectomy was performed The uterine mucosa had a rigid white opaque appearance except near the insertion of a tibrous polyp where it appeared to be softer Microscopically the mucosa was generally epidermized from the upper part of the cervix to the fundus as a result of a long-existing pyometra Two layers could be distinguished in most of the areas a markedly hornified and a proliferating germinative qualitively sufficiently atypical in a few areas both on the surface and in the glands to arouse suspicion of a mahamant change but for some time it was regarded as a benign endermization. Subsequently however you Franque discovered in a section of the anterior wall an area in which the atypical character of the cells the heterotopia and stroma invasion appeared to justify the diagnosus of carcinoma. In this area a figure is shown of atypical cell growth bursting through the membrana propria at the fundus of a gland, while the epithelium nearer the mouth of the gland appeared nor mal. In this connection Sitzenfrey s observation of another case 28 years of age is important. After a manual extraction of the placenta and a puerperal infection atypical bleeding occurred over a period of two years during which three curettings were per formed The first curettings showed a very marked overgrowth of both surface and gland epithelium in association with the changes of a diffuse chronic endometritis, but there

Slight p thelial prol feration

were none of the features of a neoplasm. The subsequent curettings showed a marked regres ion of the process in the last only a few places presenting a slight stratification of both surface and gland epithelium. Similar changes of benign epidermization were observed by Hengge (17) in two cases. 44 and 40 years of age.

Glandul ir hypertrophy and hyperplasia The glandular type of uterine cancer presents greater difficulties in the diagnosis of its incipient tage than the other forms because the preservation of the normal gland type pervits in so many instances until the amount of neoplastic structure has reached bulks proportions. The frequency also of advanced grades of gland hypertrophy and hyperplatia in menstruation pregnancy and chronic inflammatory conditions adds to the difficulty making it at times quite insuperable The clum of (cbhard (14) that a malig nant adenoma arises by a gradual transition from the ordinary form of hypertrophy and hyperpleta is not apported by the majority of pathologic Baccker (5) however re port a case in which during a period of tenveir the utern was curetted o times. lag 4 Small mocous pol p Excessa epidermok metaphesas

growth is undoubtedly correct but to the writer it seems reasonable to make an inter pretation other than that such a proliferation was imply part of an acute endometritis The argument that solid masses of cellular rrohferation such as are shown in one of illustration are not characteristic of early adenocarcin ma of the uterus is true but from the literature which the writer has given it seem not at all unlikely that both the surface and intraglan lular prohieration may express the presence of focal areas of metaplasia perhaps in the process of be oming leucoplacia as a result of a gonorrhora of which the patient history was said to be su piciou If so the case may be rea sonably considered recancerous.

As an additional entribution to the literature of the subject of precancerous change the writer offer the following cases which he has collected from the uterine material in the Pathological Laborators of the Cornell University Medical College

STEMBLARY

It seems to the writer that the evidence in the literature and the material which he has presented justifies the following comments.

1 As the positive identification of a malig mant neoplasm can not be made histologically until definite destructive capacity is recognized it seems reasonable to relate more definitely the other histological criterians of cancer to the developmental stage of its growth the closeness of the relation in a specific case depending upon the quality and ountity of such criteria as may be present.

2 If so we find in the study of uterine pathology numerous morphological alterations of epithelial growth which differ but little from the regenerative activity of beingn lesions but which after a longer or shorter time show features that are differentiated with difficulty from the alterations we know trufts mahemant necolagem.

The strongest support of this assumption is derived from the reproduction of types which are seen in the different stages of their ntogress. We find the atynical features of a healing erosion for example determined by the original type of the primary erosion sample papillary follicular and we find the atypical types again reproduced in the different types of fully established uterine In the writer's cases there are atypical healing erosions which are prototypes of either an epidermoid cancer or a papillar, adenocurcinoma There are leucoplacias which are prototypes of adult acanthomata There are glandular hyperplasias which lead to adenoma or adenocarcinoma. Finally there are focal areas of leucoplacia combined with adenomatou hyperplasia which may well furnish an origin for tumors designated as adeno-acunthomata. In short, for each type of fulls developed carcinoma there is a corresponding type of benign and intermediary change.

2. Clinical observation increasingly confirm the sequence of definite benign lesions in the uterus and cancer, but its evidence is thus far too scanty either to confirm or deax their histogenetic relations. In order to work out this problem a closer co-operation is required between the clinician and the pathol. oesst with the idea con tauth in mind that the morphological features of intermediary stages may exist. It is no argument against such an assumption because no tumor proces presents or follows in a given case evidence is already sufficient to show that a fully established cancer may can't for a certain time without giving gross evidence of its presence and numerous cases are recorded in which the curette ha completely removed the dream

5 There 1 no reason to assume that precancion changes without treatment at ways develop into maismant growths. We know different types of fully established tu mors have a different capacity to grow and destroy rapidly or slowly and it does not seem reasonable to assume that a developing cancer has the same momentum that a fully established tumor possesses.

6 In the study of beginning cancer of the uterus Sitzenfrey (20) Schauenstefn (21) Schottlaender Kermauner (4) and Pronai (53) direct attention to the important observation that a certain type of early cancer spreads appendically over wide areas before showing marked invasive feature. It has occurred to the writer that such a mode of growth may account in some measure for the widespread extent of the process before it receives the attention of the clinician.

7 From a practical tandpoint the decision regarding the proper therapeutic procedure in these cases should be assumed by a competent clinician

The writer desires to express an appreciation of his indebtedness to Professor James Ewing for numerous criticisms and suggestions and

also to thank Drs L Esperance Caturani and Mallett for much of the clinical and pathological material

A DETAILED STUDY OF THE PATHOLOGICAL CAUSES OF STERILITY WITH THE END-RESULTS1

BY JOHN OSBORN POLAK M SC M D FACS BROOKLY Professor of Obstetrics and Gypecology Long I hard College Hospital

ROBABLY no question is of such soci ological significance to the gynecologist as that of sterility. Homes are wrecked lives are sacrificed and for tunes lost, all because of the mability of a woman to conceive or to successfully bring torth the fruits of her conception Certainly no subject taxes the resourcefulness and ingenuity of the gynecologist more — Do what we will many women from one cause or another are destined to remain fruitless

It would seem from an extensive study of

our case records that the number of sterile women is increasing at least an increasing number is applying for relief. Let a large majority of those who apply present such gross lesions that little or nothing can be done to help them.

We may define sterility as the inability on the part of the woman to produce a living child This inclusive definition is propounded so that we may include in this discussion the part which syphilis plays in the etiology Sterility may further be divided into the socalled primary sterility where the woman has never been pregnant, and the secondary type where she has borne a child or has had a miscarriage and remains sterile thereafter. In this study which is a personal review of 798 case histories of patients from the writer's rivate practice we will attempt first to ana type the many etiological factors which have entered into the causation of this symptom second to discuss the treatment of the individual case based upon an etiological diag noels, and finally to summarize our end results, in the hope that this contribution may add something to this already overwritten but unsolved subject.

It must be primarily admitted that conception depends first upon the perfect consummation of the sexual set record on the
proper fecundation of the ovum, and third on
the proper nounshment of the impregnated
ovum during its growth and development
after its final location in the decidual bee
It is thus apparent that certain conditions
are essential for conception. Findley has
tersely summanced these as follows:

- r The deposit of semen containing active living spermatoroa in the upper portion of the vigura.
- 2 The passage of the healthy spermatozoa to the ovule through the cervix into the cavity of the uterus and into the tube
- 3 A healthy ovum which has uninter rupted transit from the overy and after im pregnation, through the tube into the uterine cavity
- 4 A decidual bed for the impregnated ovum to find a permanent resting place in the endometrium until the period of viability

These conditions entail a healthy male producing a healthy active, well-developed ong dilated operanatoxold capable of rapid movement through the semen. Further more, the seminal discharge should be free from infective bacteria. For these rea sons, the husband of each woman in this series has been subjected to a most exacting examination by a competent unclosust. This examination has not only included an investigation as to the potency but as to the presence of past or present infective disease. The passage of the spermatoroon through through the production of the presence of the pre

the cervix is dependent upon the activity of the particular spermatozon and the amount character and reaction of the glandular secretion from the certis. Acids in very weak dilutions are destructive to the spermatozon and thick muco-pus acts as an almost insurmountable barrier to the progress of the male element.

Proper ovulation depends on the efficiency of the individual ovary. This implies a healthy egg bearing area and the free delivery of the ovule through the ovarian tunic. Consequently conditions which have resulted in a thickening of the tunic militate against conception. Chronic inflammatory changes, prolonged acute infection, fatty degeneration tumors adhesions and senile atrophy all impair the egg-producing quality of the ovary as well as tend to thicken the tunic to such an extent that ovalar rupture may be prevented.

The proper transit of the ovum from the ovary to the uterus requires a healthy patent fallousn tube Fecundation is supposed to take place at the outer end of the fallopian tube. from whence the impregnated ovum is propel led along the course of the tube into the uter us where the endometrium has been prepared by the development of a decidua for its reception and permanent nutrition. Hence con ditions which interfere with this free transit may be accepted as causes of sterility a tube may not be patent to an impregnated ovum, its lumen may still be sufficient to allow the passage of the spermatozoon and impregnation of the ovule in its dutal por This is shown by the great frequency of tubal pregnancies, occurring after long periods of sternity which are due to the results of chronic inflammatory disease

The conditions of the tube which may im pair the transmission of the impregnated ovum are either congenital or acquired. Of the for mer we may mention tortions constrictions angulations, and diverticula, while acquired lesions are commonly the result of inflamma tory processes, which either occlude the himen or destroy the epithelial lining of the tube or produce pertubal adhesions which distort the tube and thus prevent the passage of the ovum.

On arriving in the uterus the impregnated ovum locates in the decidual bed prepared for its nourishment which usually is situated just below the uterine ostium of the tube on the anterior or posterior wall of the uterus and unless the endometrium has been the seat of disease the ovum develops at the site of its primary implantation. Syphilis of the endometrium may prevent implantation of the ovum or cause its early discharge from the uterus Circulatory derangements which produce hyperplastic and fungoid changes in the endometrium contribute largely to the unrest of the ovum These circulators changes may be produced by displacements fibroid tumors sexual excesses lacerations and subinvolutions and result in an endome trial hyperplasia. Such conditions change the character of the uterine secretion producing toxic discharges from the involved surfaces of both the body and cervix which may cause the death of the sperm cell and thus produce another factor which is antagonistic to the occurrence of pregnancy

The foregoing may therefore be considered the estential factors in the fecundation and the development of the impregnated ovum. Hence it may be deduced that where any of these elements are defective stenlity may result. McDonald claims that there is primarily a congenital anomaly (hypoplasia of the genitalia) in the etiology of all cases of primary sternity. This however has not been the experience of the writer who has found that a preceding salpingitis has been responsible for more cases of sternity than all other causes combined.

It is commonly admitted that the general health of the woman has much to do with the occurrence of pregnancy It is also known that men become less potent from the strain of overwork and that nervous excita bility decreases the individual's potency. Women who have become rapidly obese are not infrequently sterile. Hence it will be seen that each individual case must be analyzed as to its etiology before any form of treat ment can be considered and this analy is must include an investigation of both contracting parties for in our opinion, the operative treatment of a woman for sterility alone.

without the actual inspection of her husband's spermatozoa is not only unjustimable but frequently does actual harm to that woman and brings discredit to gynecology. Reynolds in a recent paper presented before the obstetric section of the American Medical Association offers the tollowing working hypothesis for determining the cause of sterility in the individual case.

r He states that when the spermatozoa are abundant in number normal in form and appearance furnished with long cilia and capable of rapid movement through the semen the male may be considered as satisfactorily potent. While this is essentially true our experience has taught us that the presence of infective bacteria in the semen or pro-statuc discharge even it the spermatozoa are well formed will often vitiate their potency because of the effect produced by these bacteria on the generative organs of the receiving temale

When the normal permatozoa are killed or lose their vitality overrapidly in the se cretions of the individual woman the chemicophysiologic character of her secretions furnishes an effective cause for the sterility

These alterations in the secretions of the woman which are fatal to the spermatozoa may be located in the vagina in the cervix in the body of the uterus or in one or both tubes. Any of these secretions may exist with normal secretions above it but altera tions in the secreting surface in any of these localities usually vitiates all the secretions below it owing to the admixture which takes place for acids in very weak dilution are rapidly fatal to the spermatozoa Finally when the spermatozoa are observed to pene trate without apparent lo s of vitality to the fundus of the uterus and to survive there for a normal length of time dehicient quality of the ora may be considered as the probable cause of the sterility Lade estimates that there are 2, 500 000 spermatozoids in a single ejaculation and it is stated that the spermatozoa will not live longer than twelve hours in the acid secretion of the vacina, vet in the normal secretion of the uterus and the tubes they will commonly retain their ac tivity and vitality for ix or eight days

Leonold a case the woman had not had sexual intercourse for thirty seven days prior to the abdominal acction which he performed when active living spermatozoa were found in large numbers in the fimbrinated end of the tube We have frequently noted during microscoole examination of the withdrawn semen the effect of the mucopurulent secretion from an infected cervix on the activity and life history of the spermatozon. They may be seen struggling around trying to free them selves from the sticky mucus and finally exhausted from their struggle to push on die Hence we feel that the tight fitting plug of mucus in endocervicitis is a real obstacle to the advance of the spermatozoid. Lespinasse claims that the secretions in different women dissolve the spermatozon of different men and thus produce a sort of immunity action This is probably the explanation of why certain healthy women fall to conceive by apparently healthy males and then upon rematriage promptly conceive.

Huchner has checked up the progress of the permatoroid by microscopic examination of the spermatoroid in situs in the genitals of the woman by taking the woman a secretions at different locations at definite periods after the intercourse and in this way has determined the action of the secretions and the comparative vitality of the spermatozos at different locations in the genital tract. This has in his experiments given a direct index of the chemicophysiologic action of the individual secretions and affords vultable evidence as to the possibility of impregnation in anniticular one.

While acute anteflexion of the cervix, in racervical hypertrophy and pronounced re troversion of the uterus act as causes of after libty by mechanically removing the cervix from its position in the seminal lake they will not prevent conception unless there is some change in the chemicophynologic action of the cervicovagunal discharge

Ande from these factors already referred to certain clinical observations are worthy of mention as they contribute materially in determining the value of treatment. The average interval between marinage and the birth of the first child is seventeen months and

the probability of impregnation decreases thereafter Only 25 per cent of women bear their first child after four years. Therefore a union may be regarded as presumptively sterile when after three years of married life no child has been born. Hypoplasia of the genitalia is a common cause of sterility fantilism may be found in the uterus alone or in the uterus vaging, and external genitals. or associated with other evidence of congeni tal hypoplasia as loose right kidney justominor or funnel pelvis, long back. cannonball abdomen intestinal ptosis, small head. weak ligaments, high roofed mouth under weight and unstable nervous system. When the uterus is sufantile at retains the shape and appearance of the uterus of the girl before pu berty. It may take one of two types it may be long and slender with a small fundus, a long isthmus and a long conical cervix, or it may be shorter with a long isthmus small fundus and a small cervix, with most of the cervix placed above the insertion of the vagina and but little projecting into it. The first type has usually a marked anteflexion while the second is frequently associated with marked narrowing of the vagina in its upper part. The infantile uterus usually has a long isth mus with the plice palmate of the mucosa of the isthmus well marked and longitudinal instead of being thin and horizontal or twisted. The varing is commonly involved with infantilism of the uterus. This takes the form of a narrowing particularly of the upper part of the vagina, thus obliterating the seminal lake consequently instead of being balloon or pear shaped with the largest end upward, the varing is tubular or sausageshaped. As a result of this the semen is not retained where it should be after corting but is expelled from the vagina. Fruitful nor mal women retain the semen, while sterile women usually lose it. The vulva may also show signs of infantilism e.g. lack of devel opment of the labla majora or labla minora

In managing our cases of sterility we have begun with a thorough investigation of the life and functions of both contracting parties. In no case included in this report was the examination of the male omitted. These examinations were conducted by I S. Read and include investigation as to the past per formances of the man as well as for his present potency for men who have infective bacteria in their prostatic secretion can produce such inflammatory changes in the female genitalia as to prevent all hope of future pregnancy

Unless the man was potent, no attempt was made to improve the condition of the woman as regards her sterility though many women were operated on for the cure of com plicating lesions If the man was found potent the woman was put through a thorough and painstaking routine beginning with her previous history including the history of her development, illnesses nutrition habits oc cupation rest, and general health. Inquiry was always made into the habits of her sexual This was followed by a general exami nation of the heart lungs nervous system stature nutrition whether emacated or obese and followed by a pelvic examination to determine the presence of anomalies at the vulva, of the vagina in the cervix or uterus or the presence of the results of in fection as shown in Skene's glands in Bar tholin's glands in the cervix in the uterus tubes ovaries, and adjacent peritoneum

The reaction of the vaginal and cervical secretions was thoroughly investigated and the presence of gross pathology in the fornices noted A Wassermann test was made in all of those who presented themselves with his tones of abortions or premature labors with death of the feetus To make this study 708 case records have been reviewed. Two hundred and thirty one were found to be inaccurate or incomplete the patients failing to return for subsequent examination or the husband s record having been omitted or for some such reason these histories were excluded from our consideration making a total of 567 from which we can draw our con clusions From this number however there must be some further deductions such as those cases where the man was impotent having asperma or deformed and sluggish spermatozoa or where the original infection remained uncured These cases total up to Furthermore we have excluded those women who were found to have such gross lesions of the uterus and adnexa as to bar

them from even the possibility of pregnancy and those constitutional conditions as car diac decompensation and diabetes which should forbid conception Of the former there were 70 of the latter 6 Subtracting these cases we begin with 427 women in whom pregnancy i a possibility these however presented such pathology that we could not say that conception was even probable For this reason I propose to consider the chology and the end results of the several forms of treatment instituted in two general classes. In the one we will in clude infantili m and congenital anomalies 73 normal pelvi free from circulatory or inflammatory complications 146 plicated retroversions 20 and infracervical hypertrophy 5 making 244 in all While in the second class we will place the remain ing 183 cases all of whom presented some evi dence of the results of an infective process at one or more locations along the genital tract It is intensely interesting to note the frequency with which infection has invaded these several susceptible points. Our rec ords show that the glands at the introitus were infected 43 times while 104 presented an endocervicitis with a mucopurulent dis charge These were complicated with a posterior parametritis in 78 instances Fibroid tumors of varying size and of the subperi toneal type producing no symptoms and only discovered in the course of the examina tion were recorded in 54 cases. Ovar ian cysts varying in size from that of an orange to that of a seven months pregnancy was the apparent cause of sterility in ten instances The results of infective processes in the tubes were found in 90 cases These were almost always associated with inflammatory or cystic changes in the ovary In 11 cases the tubal infection had extended to the pelvic pentoneum and the patient though presenting no gross lesion which was palpable at the examination was the subject of recurrent attacks of pelvic peritonitis each of these cases a double hydrosalpinx was the resulting lesion Retrodisplacement of the uterus complicated by tubal or ovarian disease was noted in 61 women Prolapsed ovaries palpable and tender often producing severe dysparcunia, were relatively frequent, as we find that they were noted as a complicating lesson in 92 hustories. Only three patients with acute vaginal inflammation presented themselves. In 2 of these the Neisserian bacillus was isolated. The other showed numberless diplococca that would

not stain gram negative. In the first class which includes all the cases of infantilism, mention should be made of the frequent association of bony pelvic anomaly Funnel pelvis, male pelvis and justo-minor contraction were noted with such frequency that we feel that the subject should have more consideration than has been given it by the gynecologist in the past, for it seems questionable when a woman has a definite bony pelvic deformity whether we are right in employing operative measures for the cure of her sterility when we know she will have a difficult operative labor Certainly the patient or her husband has a right to the knowledge of these facts. In the 73 cases recorded as having an infantile uterus, bony pelvic anomaly was recorded 41 times. This was shown in the short external measurements, the depth of the symphysis pubes a narrow subpuble arch, the short bisischial diameter or faulty inclination of the pelvic brim.

TREATMENT

The treatment, as may be supposed from a glance at the foregoing statements, was in all cases directed toward the correction of the existing causative lesion. In the first class, this included the employment of alixaline douches, of the graduated dilators, the Hald win or Davenport stem, ductission of the crvix, after the methods of Dudley or Poxid amputation of the cervix, and correction of uterine displacements.

In the second class both local and operas tive measures were employed. In those cases of uncomplicated cervicits and endocervic tits where the tenancous mucous plug presented the obstructing lealon the mucous was removed with peroxide of hydrogen on a rotary applicator or with a Bler suction apparatus and the mucous setrilized and an iodized phenol solution applied and the pattent directed to follow this application with

douches in the recumbent position before re returng using a solution of bicarbonate of soda, a tablespoonful of the soda to a quart of water Vaccines and destruction of the cysts with the electric cantery knife have also been employed. but our best results have been obtained from simple antiseptic measures. Women who have repeatedly aborted in whom the Wassermann test was reported negative were curetted and the cavity of the uterus thor oughly todized by packing the uterus with strip gauge soaked in rodine This was left in place for twenty minutes and was then removed. These patients were then advised not to cohabit for a period of three months. In the meantime special attention was given to improving the condition of their general health, by exercise tonics and fresh air Those presenting large fibroids not involving the uterine cavity had the tumor removed by invomectomy Small tumors received no surgical consideration. In the 10 cases of large ovarian cyst unliateral cophorectomy resulted in 8 of the women becoming preg nant. From this observation it would seem that a large cyst of one ovary militated against the proper functioning of the other ovary until that cyst was removed. Infec tive processes in the tubes were dealt with by undateral ablation, bilateral ablation with resection of the uterine ends or of the fundal segment of the uterus, or by salpingostomy Frequently it was found that the inflamma tory process had passed through the tube and time had allowed considerable resorption. and that it was the resulting adhesions which had closed the abdominal ostium and embar rasses the ovarian function. Freeze these and suspending the overy has frequently re sulted in pregnancy. In the series of retroversions complicated by tubal and ovarian disease all the women were subjected to abdominal exploration and investigation. In these the tubes were freed from adhesions. ablated or resected the ovaries suspended after the method suggested by my associate William P Pool, and the round ligaments shortened by following one of the techniques suggested by Webster Gilliam Montgomery Coffey or Neel.

Of the cases of prolapsed ovary we have

found that an ovary out of place has its tunic thickened from circulators stass. So we have been in the habit of suspending such oranes after puncture of the uperficial cysts to reduce their weight and have thus established a better ovarian circulation. No resections have been done except in six cases of large white ovary in obest women with amon orrhoza where the tunic was extensively thickened. In these cases a large wedge shaped piece of the cortex was removed and the area of exclion closed with the catgut sutures. The ha re-established menstruation in all six cases and resulted in a pregnancy in three.

In the 13 cases of congenital anomalies which include extreme antiflexion of the cervix with deep posterior invagination antiflexion of the body and cervix and infantile uterus the tollowing corrective operations were done. In the antiflexions of the cervix in which the invagination of the posterior lip was 4 to centimeters or more in length a posterior discission after Dudley's technique was always elected in order that the cervical os so constructed could be placed in the seminal lake. In the antiflexions of the body alone we have elected Reynolds procedure combined with the use of the intra uterine stem (Baldwin) In antificxions of the body and cervix our procedure has always been dependent upon the amount of cervical in vagination. It this was considerable a posterior discresion in conjunction with the Rev nolds anterior colpotoms will traighten the can'l On the other hand when the portio was short gradual dilatation an anterior colpoplasty and the introduction of a glass stem often produced rehef

In the true mantile uterus it is que tion able whether much should be done. Our only prignanty result in the type have been two clopics and live miscarriages for not only is the animaly in the uteru but in tubes corner and vagina and the dy menortheas which i preminent is only temporarily relieved by operation. In this class we doubt it any plastic prescure in it much avail as we have found that the presence of curs in a mall vaginal embarra see scrud relations. Slow dilatation with Hegar's sound up to 16 to

a millimeters, and the introduction of a Day enport stem ha afforded some relief but no infantile uterus in the lenes has developed a pregnancy and usne to term Seven have conceived the two ectopies referred to above and in , the impregnated ovule has reached the utern and developed there only to end in an abortion at the second or third period Included also in our fir t general clasin cation are 140 normal pelves tree from cir culatory or inflammatory changes of any sort These women had been married for periods of three year or more and had never been pregnant before applying to u for relief The husband were potent. The reaction of the secretion of the vaginal vault was deter mined in each case. One hundred and nine showed varying degrees of readity nation of the semen in situ in these cases showed many immobile spermatozoa. In all who gair an acid reaction alkaline douches of soda bicarbonate and soda phosphate one ounce to the quart were idvaled to be taken on a douche pan after retiring Pregnin vice sulted in 75 or about 10 per cent, making this our most uccessful series. Thirty seven showed no change in secretion vet only 4 have become pregnant is the result of local treatment. No operative procedure of inv sort was done in this appare itly normal pel This rather goes to confirm the theory that certain women are immune to impregnation by certain men

Of the o uncomplicated retrover ions it were reportable and could be maintained in position with a pessary. Six of these women became pregnant while o be ause of a deep posterior invagination of the cervix could not be held in place with a support. These were operated on by the Web ter Baldy or Gilliam technique and a Dudley discission. Of these, whave become prignant. This shows conclusively to my mind that the position of a cervix in its relation to the seminal lake has much to do with conception prival of the permatozoa are not destructive to the life of the permatozoa.

Intravaginal hypertrophy of the portio has given us not only the best arrival cures but amputation of the hypertrophiad portion of the cervix has been followed by pregnancy

going to term in each of our cases (5 in all). In the second class made up of 183 women presenting some evidence of the results of an infective process, post partal post abortal or gonococcic in origin pregnancy has been relatively infrequent. Of the rot, women subjects of endocervicities with a mucopuru lent discharge only 21 became pregnant Eight conceived as a result of one local treat ment in which the mucous plug was removed with a bicarbonate paste and the canal

swabbed with iodized phenol. Three be

came pregnant promptly after the glands

were destroyed with the cautery and 10 following the persistent use of the carbonate

of soda douche.

Of the 90 cases which were found to have the results of infective processes in the tubes uterosacral ligaments and cerval canal the intra uterine and tubal pregnances are equal ly divided, there being three of each. The abdomen was opened in all of these patients because of the history not because of the history not because of the gross pelvic findings. There was invariably present a history of infection, with sterility dyspareunia and local discharge. Tubal ablations were done 55 times resections 31 times, and irecting of adheaons in 30. Two ectopics occurred in resected tubes, against a latra

uterne pregnance. One ectopic occurred in a freed tube but no uterine pregnancy. Of the 54 fibroids, myomectomy was done in 20 and hysterectomy in 34. Six pregnancies occurred following myomectomy 4 going to term. Following the 10 unilateral ophor ectomies for large ovarian cysts, 8 women became pregnant.

One hundred and thirty two uterine and 3 ectopics are the sum total of pregnancies occurring in 358 women in whom conception

was a probability or 37 per cent.

This study has shown us that—

1 Very large number of the sterility cases applying for relief have no chance what ever of becoming pregnant, as the pathology is such as to make conception impossible

2 The male is largely responsible for our poor results in treatment.
3 There is a definite chemicophysiologic factor in conception at present unexplainable.

which is a cause of preventing conception.

4. Operative procedures on the uterus, except amputation of the hypertrophied por too have but a slight influence on the end results in the treatment of sterility and finally that each case must be individualized and both contracting parties carefully studied

before any trentment is inaugurated

SYPHILIS OF THE BODY OF THE UTERUS'
BY CHARLES C. NORRIS M.D. FACS. PRILADELTHIA

THE antiquity and frequency of syphilis is well known. It has been estimated that from 10 to 15 per cent of the urban population of certain European cities is syphilitic. In some of the hospitals in this country the percentage has been found considerably higher than thus. The disease is from two to four times more frequent in men than in women probably from 1 to 4 per cent in women would be a conservative estimate

It is only since the discovery of the spirochata pallida in 1905 and the development of the Wassermann test two years later that the true frequency of this form of infection has become recognized.

In spite of the prevalence of syphilis it is remarkable how seldom the disease has been observed in the body of the uterus. In a review of the literature one cannot but be impressed by the pacuty of reference and our incomplete knowledge of this subject. A review of the Index of the Surgeon General's Litrary to 1014 showed but thirty-six refer ences by thirty-one authors, and reference to the Index Molecus Irom 1000 to date dis-

closed only eight contributions to the sub-

ject. The majority of the modern gynecologic textbooks have either no reference to syphilis of the body of the uterus or at most the subject is dismissed in a few sentences A pleasing exception is noted in the recent work of Krankl' in which a chapter is devoted to syphilis of the uterus. This contains an excellent review of the literature. Our reviews showed rather frequent reference to syphilitic manifestations localized in the cervix such as chancre mucous patch gumma and a condition which the obstetri cians term ngid cervix which is prone to produce dystocia Lesions of the cervix however do not fall within the scope of this paper so that we shall omit them and con sider only syphilis of the uterine body

PATHOLOGY

Various classifications for the syphilitic lesions of the body of the uterus have been suggested. The amount of material from which to draw conclusions is as yet rather small. Many cases have been reported as syphilis of the uterus which are at least of doubtful authenticity. This is especially so of the period prior to 1905. In many cases uterine harmorrhages have been attributed to syphilis which are open to doubt.

It is theoretically possible that the endome trium may be the seat of a primary sore This is however unproved. The fact that the spirochæta pallida may become attached to or even possibly enter spermatozoa is well recognized. In recent years the fre quency with which cases of syphilitic infection in women without evidence of a primary sore being demonstrable have been recorded make this possibility worthy of consideration the other hand it is well proved that the pirochæta pallida exhibits a strong pre dilection for squamous epithelium in the primary infection. This however may be the result of misplaced reasoning as the areas naturally most exposed to chancre are covered with this type of tissue Two other explana tions offer themselves for those cases in which no primary sore has been demonstrated the one that the disease has been hereditary and

Liepmann Kursgefantes Handbach der gesamten Frasenheil kunds Liepzig: 914, is, os. the other that the chancre has been present in the vagma or cervix and has been over looked. The fact that chancres produce mild symptoms and are consequently not looked for offers a probable explanation in many cases. It must be remembered that in women a chancre does not leave behind it such definite evidence of its previous existence as it does in men and that the period of its existence is more transitory than in the male. The possibility of the primary sore occurring within the body of the uterus should how ever be considered.

In 1011 Hoffman' presented before the Society of Obstetricians and Cynecologists in Berlin an interesting specimen of gumma tous endometritis The patient from whom this specimen was obtained died of chronic sepsis a few weeks after delivery. At post mortem gummata and other evidences of syphilis were demonstrated in organs other than the genital tract The endometrium in this case contained numerous small gummatouslike tumors the tissue lying between these was intiltrated with small round cells and pre sented other evidences of a subacute or chronic inflammatory reaction For the most part the normal constituents of the endome trium were unrecognizable being replaced by the cummatous tissue. This in some areas was two or more centimeters in thickness The entire endometrial cavity was more or less involved. The uterine body was en larged and softened

A more common form of syphilitic endome truts manifests itself by changes in the glands and stroma the latter being chiefly involved. It is characterized by changes in the blood vessel walls and condensation of the stroma. Exactly how frequently this condition exists is not known Chases' recent conclusions regarding the frequency of syphilitic endometritis in general require further confirmation. Recasen' has described a form of syphilitic endometritis in which the mucosa is thickened and hyperplastic. Ulceration of the endometrium is not infrequent and resulting scars may also be

Hoffmann Zischr f. Geburtik Gynnek Stattg 9 kmz, 8 Chase J C. Tex St J M 9 3 k, 93 Recasen, 8 Ann d. Acad d obst. (etc.) Madrid 9 fv 04. observed. This is particularly likely to result during the tertiary stage. Such lessons have been described by Franceschini. The histologic picture in specimens of syphilitic endometritis probably varies not only with the stage of the disease but with the period of the menstrual cycle in which the tissue is examined. The underlying musculature is usually more or less involved. Whether or not mucous patches or other secondary manfestations occur in the corporal endometrium is unknown. Many authors' (Franceschini Chiarleoni, Rille Fasola Spinelli Morisani and La Torre) believe that such lexions are not uncommon and that in some instances they produce leucorrhom, dysmenorrhom, and uterine pain.

Lesions of the invometrium may be divided into (1) a more or less diffuse metritis which is usually accompanied by an inflammation of the endometrum, and (2) gummata. In the former condition the uterus retains its nor mal shape, it may or may not be enlarged and is usually harder and firmer than normal In at least one reported case the uterus was atrophic. The walls of the uterus are lacking in their normal elasticity and in some in stances have been almost cartilagmous in consistency An cedema of the uterus and pen utenne tissues has also been observed. In syphilitic metritis the blood vessels as a rule present the chief changes. The lessons are not peculiar to the uterus but are those common to syphilis of the more frequently attacked areas of the body Morisani' as a result of histologic studies of syphilitic uteri considers anglosclerosis of frequent occurrence. Findley in his excellent textbook considers this subject in detail and apparently concurs in this opinion. A fibrosis of the uterine musculature accompanies the blood vessel changes.

Gummata of the uterus may be single or multiple and vary considerably in size but are usually moderate in dimension, and

differ in no respect from similar lesions arising elsewhere in the body. A student of the literature pertaining to the pathology of synhilis of the uterus cannot fail to be impressed with the paucity of well authenticated cases and with the fact that as yet our knowl edge of this subject is far from complete From a clinical standpoint the question of so-called syphilitic utering harmorrhages is of perhaps the greatest interest. The common practice of attributing symptoms which clear up under antisyphilitic treatment in patients exhibiting a positive Wassermann test to a syphilitic origin is at least open to scientific doubt Probably the bleeding in many of these cases is properly attributed to syphilis, but on the other hand with a disease as frequent as syphilis and taking into consideration the numerous and often obscure non avahilluc conditions which cause be-mor rhage it is but reasonable to assume that combination of these may occur and the harmorrhage be in some instances due to a condition totally apart from specific origin. The writer believes that this is a fertile field for further investigation. With the increasmg facilities with which the spirocheta pallida may be dimonstrated and the fact that curettage is a frequent and in many cases a justifiable method of treatment of uterine harmorrhages of obscure origin it would seem not a difficult procedure to work up a series of cases from which a definite basis of histologic study could be made for example a series of specimens in which the spirochata pallida was demonstrated was obtained and these were then studied from a histologic basis the results of the latter would go far to establish upon a firm basis the pathology of syphilis of these structures and we would then be in a position to state positively whether or not certain histologic changes were sufficiently characteristic to warrant a diagnosis of syphilis or whether we should have to depend upon the demonstra tion of specific organism. With the possible exception of gumma it is doubtful whether a histologic verification is sufficient.

The German views pertaining to this subject are well expressed by Meyer. He states

Mayor, ? Dectards used Websacker tasts, atms, 163.

Motorco, T. Arch disented posts. Napolit, so 10, 57 Findley P. Dressen of Women, Parkidelphia 2013, p. 32 from turn an empasses habitagenoby)

that very little is known about the syphilitic inflammation of the uterus but that Doeder len 1 Weber and others are of the opinion that there is no characteristic change in the uterine mucosa which can with certainty be described as syphilitic

SYMPTOMS

These naturally vary with the character With the present unsatisfactory of the lesson status of the pathologic changes produced the symptomatology is necessarily uncertain Undoubtedly hæmorrhage is the symptom which has attracted the most attention We have already mentioned the fact that hemorrhage is frequently attributed to a syphilitic origin without convincing proof Hæmorrhage is by no means a constant symptom in endometritis or metritis in general although variation and menstruation are of frequent occurrence In such conditions the ovaries are usually more or less involved in the inflammatory process and whether or not the menstrual irregulation occurring in these cases is the result of the uterine or the ovarian involvement is open to doubt. This naturally opens the entire and much debated cause of such harmorrhages. Time will not permit a discussion of this subject it suffices to say that the author is of the opinion that inflammation in either the ovary or the uterus may under certain cir cumstances result in menstrual irregularity but that in the majority of cases the ovary is the governing factor

The most frequent form of hæmorrhage described is menorrhagia. In 1906 Dreyer-collected from the literature fourteen cases of hæmorrhages attributed to uterine syphilis. A vear later Muratow-called attention to the fact that syphilite hæmorrhage from the uterus is not so rare as we might think and as evidence of this he mentions the cases of hemorrhage which do not respond to the ordinary styptics and curettage but do well under specine treatment. He points out that in such cases the uterus may be neither enlarged nor painful but is firm in

Doederken Vest Hundboch der Gynnek Weisbaden poz Dreyer A. Dermat Zisch Berl. 300 mu s Muratow A. A. Zentralb f. Gynnek Luping, 907 mm, \$30.

consistency and the cervix often hypertmic Hæmorrhages in young girls Muratow be heves are frequently due to a latent form of hereditary syphilis In 1909 Falk demon strated before the Berlin Obstetrical Society a case of luctic ulcer of the portio associated with syphilitic metrorrhagia which disap peared under specific treatment. Recasens reported six cases of syphilitic metritis five of which were cured by treatment, but in the sixth case carcinoma of the fundus was sus pected and a hysterectomy was performed but upon microscopic examination no cancer was found Merrowsky and Frankenstein have described three cases of tertiary syph ilis in which amenorrham persisted for 6 years in two cases and for 8 years in the third In two of these the manses returned after the exhibition of specific treatment and the third menstruated vicariously through the nose after treatment was instituted authors attribute the amenorrhoa to either constitutional causes such as often produce amenorrhœa in subjects of pulmonary tuber culosis or to a syphilitic cophoritis

McIlroy Watson and McIlroy applied the Wassermann test to one hundred gynecol ogical patients in only six of whom was there

a clinical history of syphilis

The test was positive however in forty three cases negative in forty-eight while in the remaining nine cases it was doubtful They state that their results show that cases in which uterine hemorrhage apart from tumor is the principal feature syphilis very frequently is present. They are also in accord with Muratow (cited above) in the belief that some of the cases of menarchial hemorrhage are of syphilitic origin ther work along this line has been done by Whitehouse • He studied sixteen patients with a clinical diagnosis of chronic metritis and subjected them to a Wassermann test Only one patient furnished a history of lues All of the others strongly denied such a

possibility and there was no reason to doubt them. In spite of this, however seven cases gave a well marked positive reaction. These patients all applied for treatment on account of pelvic pain irregular and profuse utenne hemorrhage and watery or mucopurulent discharge.

The physical signs obtained upon himanual examination were those usually regarded as characteristic of chronic metritis namely a alight but uniformly enlarged uterus, firm in consistence, and tender upon paluation. The specimens removed from these cases show well marked fibrosis and peri and endarteritis. Whitehouse believes that a true gumma does not occur in the cornus uten. He also calls attention to the fact that although pyometra is usually attributed to malignant disease, he has observed two cases and records two others from the practice of another physician in which pyometra occurred in patients with well marked tertury lesions and no evidence microscopically or macroacopically of malignant disease. He has never been able to demonstrate the spirocheta pallida either in sections of the uterus or in the menstrual blood but is impressed with the necessity of testing by the Wasser mann reaction all patients who present the clinical picture of chronic metritis or fibrosis. As in all inflammation involving the en

dometrum and invometrium leucorrhica is a not infrequent symptom. Various types of leucorrhora have been described. Neumann' believes that the discharge is usually thin and moderately profuse. Pain, dyspareunia and other symptoms common to non-syphilitic metritis have been noted. As a matter of fact none of the local subjective symptoms are by any means characteristic of syphilis. The following is the report of a case of probable syphilis of the uterus.

Ago 36 years white married 3 children, 3 mlscarriages. Family history negative. Chief symptom menorrhagia.

P criest kiney Until the past five years has been a strong healthy woman. Married at 24 years. Three children, 1 8 and 7 years, healthy and strong. Six years ago the husband contracted syphfile and upon the development of the secondaries was placed upon treatment by his family physician.

Humana, Index Syphite, Venne Spir.

At about this time he undoubtedly injected his wife. She however gives no history of a primary sere, but the development of typical secondaries and their disappearance under treatment established the diagnosis. During the past six years or since the onset of her symbilis the nationt has had three miscarriages, advanced respectively 2 3 and 5 months the last of these all months ago. The nationt has been treated by her family physician for syphiles until nine months ago (mixed treatment) when treatment was discontinued by the patient as she believed herself cured Until coming to the University Hospital no Wassermann tests or attempt to demonstrate spirocheta pallida had been mad

P sent llues A five months miscarriage occurred six months go one month later mesor rhagia developed Instead of the periods as former ly lasting at 5 days, they now last 8, to or a days. The bleeding is for the first 6 to hours moderat in amount but by the second day is profuse, bright red and takes on the character of a severe hemor hage. This continues for a varying period of time and gradually diminishes, a moderate mild flow continuing and Lating for week or more. As a result of the last three bleedings deep to the usual treatment such as rest in bed, see errot, etc. so much blood was lost that the patient has been much weakened. When brought to the hospital the retient had been bleeding for a days. For the last three periods patient has been bedridden during and for some time foll wing the flow Between periods and especially during the days immediately following th cessation of the bleeding there has been a profuse thin, non-odorous leucorrhosa. Distincts, weakness, headaches, and other evidences of anemia have been present. All these symptoms are worse toward the end of and immediately follow ing the flow There has been no pain. The appetite is variable and the bowels at times constipated.

Physician s communation This reveals a moder ately well-nourshed woman. The heart, lunes, liver and kidneys are normal. Blood, harmoglobin 52 red blood-corpuscies, 5,000,000 white blood corpuscies, 4500. Wassermann strongly positive. Abdominal examination, egative.

Pelvic examination negative. Outlet multiparous. Good support in anterior and posterior wall, cervit normal in size and shows a well healed bilateral laceration. It is softer than normal and the canal is patulous, slightly dilated, just admitting the tip of the inger The uterus is normal in arre, shape and position. It is movable and not unduly tender even on deep palpation. The adnexe are normal. A careful examination fails to reveal any evidence of the site of the primary sore.

Owing to the lack of any assignable cause for the hemorrhage, a diagnostic curettage was advised. Operation. On moderate traction with tenacu

lum during an effort to draw down the cervix the instrument to e through the cervical tissue. During the curettage with a Martin curette the funder was perforated. No undue force had been used. In view of the evident softness of the uterus the fact that a perforation was present in the fundus the history of severe and persistent bleeding the age of the patient and the fact that he already had three hving children a hysterectomy was decided upon and performed in the usual manner. The tubes and ovaries were not removed.

Containment was normal. The patient was placed upon a tonic and one administration of advarsan was given intravenously before leaving the hospital and her family doctor advised as to the condition so that antisyphilitic treatment could be

continued.

Pathologic description The specimen consists of curettage and uterus.

Curelings These consist of a moderate amount of macroscopically normal endometrium.

Uterus This has been removed by supravaginal amputation. It is normal in size and shape, measuring 7 5 centimeters from the point of ampu tation to the top of the fundus 6 centimeters laterally and scentimeters anteroposteriorly (through fundus) The endometrial cavity presents no abnormalities an incomplete curettage has been performed It measures 5 5 centimeters in depth. The myometrium is normal in thickness and is rather paler than normal cuts with ease and in the vascular layer large numbers of blood vessels are present the cut ends of which are remarkably prom These and the friability of the tissue are the chief peculianties of the specimen The myome trium is so soft that the walls may be squeezed through with ease at any point with the thumb and forefinger In the posterior wall of the fundus is a perforation which will admit a small lead pencil

Histologic describition Endometrium The en dometrium is normal in depth or perhaps slightly thickened. The surface is fairly smooth and is covered with a single layer of high columnar cells The superficial layers of the stroma are infiltrated with blood scrum, and chronic inflammatory prod ucts. At some points subepithelial harmorrhages are present. In one of these the surface epithelium has been desquamated. The deeper portions of the stroma are condensed and fibrous. Many blood vessels are observed. The majority of these possess well-developed muscular walls in which marked aderosis is present. Scattered here and there are areas of chronic inflammatory reaction. The line of demarcation between the mucosa and underlying muscularis is well defined. The glands are normal in number size and shape and are of the interval type. The specimen thus resembles an endometrium the seat of a chronic diffuse inflam mation with marked angiosclerosis

Myometrium Four sections taken from various portions of the uterus. All present the same general histologic character Immediately beneath the endometrium there is an ill-defined zone of chronic inflammatory reaction which gradually fades into the deeper and uninflamed myometrium. The

blood vessels are more numerous than normal and possess unusually thick walls. This is more marked in the media. The arteries and veins are both affected but the changes are more pronounced in the former. In some instances the blood vessels are six or seven times the normal size and in some the degenerative changes involve not only the vessel walls but also the adjacent myometrium peri arthritis In one or two areas thrombi are present while in a few fields vessels are observed in which as a result of endarteritis complete obliteration of the lumen has occurred. In many areas extravasations of free blood are present. The lympathic spaces The fibrous and muscular tissue stain poorly in the eosin and hæmatoxylin preparations. Much free serum is present as a result. In some areas the muscle-tibers can be seen partially separat In some helds these cedematous areas are more marked than in others but are quite as numerous in the fundus as in the lower portion of the uterine body The chief histologic characteristics in this specimen are the angrosclerosis affecting chiefly the inner coats of the vessels and the areas of ordema above described. Section fixed in Zenker's and in 4 per cent formalin solution and stained in hæmatoxylin and eosun Weigert's fibrin staln and Van Gieson a stain.

Diagnosis Syphilis of the uterus.

The histologic picture present in this speci men conforms closely to that described by other authors Whether or not syphilis produces sufficiently characteristic lesions in the uterus to warrant a positive diagnosis has al ready been considered. In this case the changes were typical of those produced by syphilis elsewhere in the body and I have little doubt as to the correctness of the diagnosis The histologic picture is not that of a subinvolu tion nor does it at all resemble those cases which are usually classified as fibrosis of the uterus Furthermore the results of histologic examination is confirmed by the history and clinical findings. This patient contracted syphilis six years ago anti syphilitic treat ment was discontinued nine months ago Menorrhagia and other symptoms of syphilis of the body of the uterus developed three months later The Wassermann test was at this time strongly positive. Whereas on account of the rarity of syphilis of the uterus all cases of the metric variety in which the spirocheta pallida are not demonstrated should be viewed with doubt there neverthe less seems little question as to the correctness of the above diagnosis

Undoubtedly the chief clinical symptom was the menorrhagia and the chief pathologic leaven the great softening and frishilly of the uterus together with the more typical changes usually produced by syphilis. Marked soft enling of the uterus has been noted by a

number of observers, but is by no means characteristic of this variety of infection Weber ¹ Bolt and others have recorded cases in which softening was a marked feature.

SYPHILITIC FEVER

IN RELATION TO GYNECOLOGICAL AND OBSTETRICAL PRACTICES!

BY FRED I TAUSSIG M.D. F.A.C.S. S. Louis

T O judge by the almost complete absence of reports concerning syphilitic fever in gynecological and obstetrical hterature it is manifest that this interesting and at times unportant, symptom has received no consideration by our confreres. The extensive work of Gellhorn and Ehrenfest has shown that syphills of the in ternal genitals is not as rare as some of us had previously supposed. My own more limited review of a series of cases in private and clinical experience, together with an analysis of the existing literature, has convinced me that syphilitic fever is also not such a unique symptom if only we would be constantly on the watch to analyze the possible factors in the cases of unexplainable fever that we so frequently observe

The diagnosis of syphilitic fever can rarely be made with absolute certainty There is nothing characteristic about the temperature curve. In the milder more common forms the fever does not rise over 100 to 100 5 with a relatively slow pulse and lasts only a few days in the severer type we have a remittent prolonged fever extending for weeks or even months with an evening rise of tem perature to 102 to 103 and intervals of a few days at a time when the fever almost ceases. The mass of evidence concerning syphilitic fever doubtful as it may be in the individual case leaves no question that syphilis is at times actually responsible for the use in temperature. Nevertheless, in analyzing symptoms we should constantly bear in mind Virchow's warning not to call everything syphilis that appears in a syphillitic person or that disappears under antisyphilitic treatment. Thus we can explain lever that disappears under antiluetic treatment, in four different ways

- The antiluctic treatment may have destroyed not only the spirochette but also septic bacteris that were the cause of the fever
- 2 The antiluctic treatment may have so improved the patient's bodily resistance as to enable her to overcome fever due to other organisms.
- 3 The antiluctic treatment may have been merely coincident with a fall of tempera ture due to other causes.
- The antiluetic treatment may actually have been responsible for the cessation of a fever due to syphilis.

On the other hand, we cannot conclude that a fever is not syphilitide because it ceases without antiluetic treatment, since we know that syphilis and all its manifestations are to a certain degree limited by the natural immunity acquired by the individual Noran we conclude that a fever is not syphilitic because it persists in spite of antiluetuc treatment, since we know that certain cases of malignant syphilis will resist all known meas

ures.

Scientific proof of syphilitic lever in any
case would require the exclusion of all other
possible causes the finding of spirochete
pallida in the blood before treatment and the

Read before the American Gymenlogical Americalus, Washington, May 1916.

simultaneous disappearance of spirochæta and fever under the customary treatment. These conditions it will of course for technical reasons be impossible to fill in more than a very few cases. In the main we must arrive at our diagnosis possible or probable by a careful estimation of the patient's history physical conditions. Wassermann reaction and the effect of the treatment.

Syphilitic fever may be divided into (A) secondary syphilitic fever (B) late secondary syphilitic fever (C) tertiary syphilitic fever

A Secondary syphilitic fever is that which we find preceding or coincident with the outbreak of the syphilitic rash Fournier states that it occurs in about 20 per cent of all syphilities The rise is not over one or two degrees and the duration three to four days so that the patient ordinarily gives it no attention At the outbreak of secondaries women often come to the gynecologist either because of local sores or on account of a complicating gonorrhoea or pregnancy. It would be well therefore for us to bear in mind that a slight rise in temperature at this time has no special significance. Whether it is individual predisposition or a virulent in fection that is responsible for the occurence of fever in one out of every five syphilities at the time of the rash it is impossible to say Occasionally we find that the fever is quite high and persistent. An illustration of this sort occuring in an obstetrical patient was noted in the following case the data of which were kindly given me by Dr Ehrenfest

Airs — 20 years old martied February 1 1915 in good health began on April 15 to have a peculiar intermittent fever disgnosed by her family physician as typhoid, that lasted for six weeks. Shorthy thereafter she was seen by Dr. Ehrenfest who found a faint secondary skin rash still visible and a suspicious sore on the labuum mnus. Widal reaction was negative and no other explanation for her fever could be found. Both the patient and her husband had a Wassermann 4+ The patient was thin and anxinc and at this time was three months pregnant. Under salvarian and mercury a marked improvement of her general condition and increase in weight occurred.

The following important additional data were obtained from Dr C Foulkrod of Philadelphia under whose care the patient was confined in January 19 1916 Owing to a nephritis and the generally weakened condition of the patient no antillustic treatment was given just previous to and after her confinement. From January 10 to February 7 the patient had a remittent fever that varied between 00 to 102 6 averaging a little over 101 every evening. There was no evidence of any form of puerperal or other infection. Breasts, perneum lookina were all normal. Finally, in view of the persistent fever, it was decided to give another dose of salvarian. On that day the temperature rose sharply from 100 4 at 3 p m. to 104 8° at 4 p m. falling to 107 2 at 6 p m. and 90,4 at 9 pm. The following day there was still a rise to 101 4 but from February 9 on the temperature did not rise over 90.

The sudden temporary rise after salvarsan has been noted by other writers (Polano Glaser). This additional occurrence of elevated temperature is clearly to be grouped as late secondary as philitic feet.

B Late secondary syphilitic feer offers greater diagnostic difficulties and is less fre quent than that coincident with the eruption Graves has emphasized the occasional recurrence of short periods of elevation of temperature associated with other so-called constitutional symptoms in syphilities for some months after the onset of the disease. He interprets such symptoms as due to the occasional outbreak of organisms accumulating in a latent syphilitie person. In such as are susceptible to elevations of temperature we may have at these times a short period of fever.

Every now and then this late secondary fever will be more persistent and have a higher range of temperature A characteristic example of this group was reported by me six years ago 1 A brief summary may be of interest in this connection

C W 23 years old contracted syphilis about the middle of her pregnancy. The following month a typical papular cruption, sore throat and adentits occurred. She was put on protiodide of mercury by her physician and the eruption began to fade. Two months later I was called to see her on account of a fever starting four days previously running up to 103 and without apparent cause. Typhoid tuberculosis prelits sepais and appendictifs could be excluded. The persistence of fever up to 103 to 103 for the next ten days induced me to deede on premature labor with the hope of clearing up the diagnosts. Dell ery of a living four and one half pound child was accomplished.

Sure Gymec & Obstet x

without trouble. The fever persisted for three days more without any apparent cause, rising to rot on the second day post-partum. I family decided on the possibility of syphilis as a factor in the fever and gave bichlocks of mercury gr 1—10 hypodermically on two successive days. The fever cassed at some and did not return

Another less pronounced case came to my service at the City Hospital March 13 1916

She was a negress who had been normally confined ten days previously No evidence of pelvic infection or other inflammatory disease elsewhere in her body could be determined. Her skin still showed typical papular syphilitic spots that had appeared several weeks previously. There were enlarged post-cervical and inguinal glands. The Wassermann was negative. During the first six days she ran a somewhat irregular fever with a mari mum of 103 She was then given two hypodermics of mercury bensonte on alternate days. The fever promptly ceased and did not return during the following two weeks, at which time she left the in stitution. In spite of the neastive Wassermann, I think we should strongly suspect syphiles as the cause of the fever in this patient.

Leblond also reports a case that belongs under this head

The nationt had to tracted syphilis during her pregnancy Under antiluetic the treatment syphilitic manifestations disappeared. Foctal movements ceased at the sixth mouth of pregnancy No treatment was given for the following five weeks. Then 714 months dead fortus was spontaneously expelled. There were no brasions in the genital tract. There was no fever for the first seven days post-partum. Without any local symptoms or explanation elsewhere in her body the patient becan to have a high remittent fever with slow pulse good appetite, and complete absence of pain or discomfort. Antibuetic treatment resulted in prompt and permanent cessation of fever.

C. Teriary sphilitic feer is much less frequent than the secondary types, but is of greater diagnostic importance. The fever is usually continuous and attended with an elevation of temperature of roz to rog Evidences of the sphilitic infection are usually absent and the symptoms have been for gotten by the patient. The diagnosis is therefore established with great difficulty and usually after considerable delay. To the 62 reasonably certain cases tabulated by Stern in roja. I was able to add 21 additional cases including one of my own making a total of 83 cases. The organs primarily affected by the tertury process in these cases were

Liver	29
Bones and joints	9
Lungs and air passages	
Nervous system	6
Spleen	4
Circulatory system	3
Hereditary	3
Female genitalia	ī
Uncertain	7

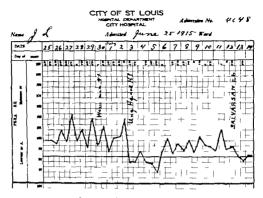

The gummatous lesions upon the skin as well as those occuring so frequently about the external genitals of women and in the rectum do not apparently give rise to this tertiary syphilitic fever Occasional slight elevations of temperature such as we had are more probably due to secondary infection of the ulcer It is the deep-seated gumma such as we find in the liver and the osseous system that is most ant to give rise to this symptom. Not merely the extent of the syphilitic in filtration however is to be held responsible. Glaser for example, reports a case of syphilis of the lung with complete consolidation of one lung but with a normal temperature. Extensive liver intiltrations occur without fever in fact, the absence of fever has been emphasized in differential diagnosis as point ing to syphilis These exceptional cases of tertiary syphilitic fever must therefore be carefully kept in mind. Abdominal sur geons have at times mistaken the fever and liver enlargement in liver syphilis for a chole cystitis. Riedel reports having made this mistake five times.

In our special neld tertiary syphilitic fever may be subdivided into-

I Cases in which tertiary syphilis of the genital tract caused the fever

2 Cases in which a gynecologic or obste trical condition was complicated by tertiary syphilis in other organs producing fever

The interesting cases of uterine syphilis reported by Gellhorn and Ebrenfest were in part attended by tertilary gunmatous infiltration of the neighboring connective tissue. I had occasion to examine most of these patients personally and some were for a time in my service at the City Hospital. In going over the temperature charts of three of these cases, those in which there was the most pronounced gunmatous infiltration of uterus and parametrum. I found that all

three ran a temperature on admission that could not readily be explained except on the basis of their syphilis. In observation \ (B L ,307-13) the admission temperature was 101 but the subsequent records are missing In observation VI (M B 10612-16) at the time of admission in November 1015 when the cervical lesion was compara tively small the temperature went up to oo 5 to 100 for 4 days after admission On her second admission in January 1010 the cervix and surrounding parametrium were converted into a nodular mass such as I had never seen except in carcinoma. Only the histologic picture could convince me that this mass was really a gummatous infiltration This woman ran an irregular fever ranging from 101 to 103 8° in the evening While there is no denying that the ulcer was see ondarily infected the syphilitic process was essentially the cause of her death and in view of the malignancy of the condition and the absence of any particular symptoms trom the secondary infection the probability is that the fever was due at least in part to syphilis

I should draw a similar conclusion from the data at hand concirning the case of malignant sphilis of the uterus reported by Hoffmann Hoffmann speaks of the case, is one of chronic sepsis following childbirth. The colon bacil lus was to be sure found in the blood culture nevertheless, autopsy findings revealed not the picture of a severe colon infection, but that of extensive gummatous infiltrations in the utcrus right tube and ovary retroperatoneal glands, lung, and liver. I think the question may furly be raised whether the lever in this case was not due to spirochate sepsis.

Turning now from these merely suspicious cases of tertuary syphilitue fever we come to one concerning which there can be little doubt as to the correct interpretation. It was reported as observation XV (Gellhom and Ehrenfest)

J L (Admission No 40,8-15) colored twenty eight years old. No miscarringes One normal confinement ten years previously. I attered hospital because of a blood tinged vaginal discharge with pains in the right lower abdomen. Examination revealed eedema of both labia majora and minora with a small typical tertary ulcer under the right labium minus and an indurated ur thrial tube. Cervix encaded in an infiltration extending to the pelvic wall. Wassermann 4+ There was in hyperfeukocytosis nor any high fever uch as you would expect with a large acute pelvic exudate du to septic infection. The bedinde notes attached to the history shows howeve that there was a rise of temperatur and moreover one that treated so distinctly to the antisyphil it retainent that

there can be no reasonable doubt f the diagnosis tertury syphilitic feer. The exact description of the changes wrought by the treatment upon the pelvic mass are equally convincing and are mutually corroborative of the nature of the affection.

The accompanying temperature-curve is very instructive. The temperature ranged from one to our from June 25 the day of admission, to July 3 the day that the patient was first put on unguentum hydraryyri and increasing dozen of potations looked. The temperature fell to normalify a few days and then begin gain to become elevated, though not as high as before. Immediately sub-curve the completely and did not enum MrRI. As not considered to completely and did not enum MrRI. As not considered to the considered to th

Cases in which a gynecological or obstetrical condition is complicated by tertiary syphilis in other organs producing fever are ocus sionally to be found. Two such cases have been recently reported by Glaser patient, the wife of a contractor developed an intermittent high fever following confinement. There was a swelling of both liver and spleen but no indication of pelvic in fection. Malana, septicemia, and typhoid could be excluded bacteriologically husband acknowledged syphilis. In spite of a negative Wassermann salvarsan was oven with sudden and complete cessation of fever and a disappearance of the enlargement of the liver and spleen.

The other case developed a persistent fever after a hysterectomy. No cause for this was apparent. A secondary laparotamy hrew no hight on the subject. Pains in the lower limbs suggested a luetic persostus. Wassermann reaction was found to be 4.4 Antifuetic treatment brought immediate cessation of fever a gain of 18 pounds in weight and disappearance of the bone symptoms.

Such cases should put us on our guard in every case of obscure persistent fever complicating a pelvic condition, to have a Wassermann reaction made and to try the effect of antiluctic treatment.

CAUSE

The cause of syphilitic fever has been the subject of considerable debate. Some in sist that we must explain it on the basis of a secondary infection with other bacteria (Rosenthal, Kirckheim) but the majority feel that the evidence at hand justifies positively the conclusion that the fever is due to the spirochætæ and their toxins. Sobern heim considers it possible that the rise of temperature is due merely to the absorption of products of these necrous and is therefore independent of the organism atself were true however we should not expect so immediate an effect upon the temperature from antisyphilitic treatment but rather a gradual cessation of fever Schlegimann and others believe that when syphilis attacks the liver we are more apt to have fever since interference with the metabolism of that organ rauses elevations of temperature this connection Stern points out the frequent association of fever in the secondary stage of syphilis with a mild degree of icterus indicati re of interference with liver function. Monier and Fournier believe syphilitic fever is more frequent in women than in men but this statement has not been sufficiently confirmed The most plausible explanation why some have fever and others do not is that put forward by Stern In syphilities without fever it is possible that only the spirochetic enter the circulation while in those having fever the spirochetæ plus their toxines get into the blood and it is the latter that produce

the rise in temperature Additional information as to the cause of syphilitic fever may come out of our study of the rise of temperature that is occasionally seen after injections of mercury or salvarsan I olano found in 12 out of 106 cases of secondary lues a temporary elevation of one or two degrees after mercurial injections reports a mmilar occurrence in 10 out of 100 cases Glaser found that such a rise of temperature after salvarsan or mercury injections given with the utmost precautions occurred with greater frequency in latent lues. He explains the symptom as due to the death of larger numbers of spirochette. The re sultant liberation of their endotoxines causes sufficient irritation to produce a mod erate degree of fever Bauer also found a rise of temperature after the first injections in liver syphilis.

For detailed hencey and description of the physical emanants: I said refer the mader to the officie by Gallbert and Eurosies a Syphilm of the Interest Counts Origins in the Refered or Syphile American (b) secological Securi

To ummarize then

The diagnosis of syphilitic tever can rarely be made with absolute certainty but we should more often consider it as a possibility and institute antiluetic measures in suitable cases

Secondary syphilitic fever occur in a mild form in o per cent of patients at the out break of the rash and at time is prolonged and more severe in its course

3 Late secondary syphilitic fever 1 o. casionally seen in a pronounced form after confinement or in gynecological patient.

4 Tertiary yphilitic tever is practically never due to syphilitic lesions in the female genital tract. ()ne such case is reported by the author. It may however complicate a gynecological or obstetrical condition and owing to the difficulty in locating the site of the tertiary lesion lead to a wrong diagnosis as to the cause of the fever. All doubtful cases should be subjected to a Wassermann test and if positive given antiluetic treatment.

5 Syphilitic tever is probably due to the reaction of the body to the toxines produced by the spirochætæ which under certain cir cumstances or in certain individuals gain an entrance into the circulation

OBSERVATIONS ON THE OCCURRENCE OF SYPHILIS IN THE UNIVERSITY OF MICHIGAN OBSTETRIC AND GYNECOLOGIC CLINIC

B REUBEN PETERSON M.D. FACS As Assess M. mc Protesses of Obstatuce and Copenings University of Machines

ORTU-ATEL) due to the thorough and enhaustive work of the referenten the participants in this symposium on syphilis in its relations to obstetic and genecologic practice can omit introductions and references to the literature and confine themselves strictly to their portions of the discussion

It is only within the past five years since the discovery of the spirochæta and the Wassermann reaction that syphilis can be said to have been studied with any degree if scientific accurate in the obstetric and gynecologic clinic in the University of Michigan Hospital Active cases of syphilis with abundant skin or mucous membrane manufestations were recognised and the proper treatment instituted but we were quite ig norant as to the extent of latent lues with the result that many cases passed unrecog nized and the patients suffered accordingly While the system carned out in the University Hospital for the recognition and treatment of syphiles is not without its faults and no doubt could be greatly improved upon it has served its purpose as a beginning and is vastly superior to no system at all

For the past year there has been a hospital rule that every in-patient should have a Wassermann taken and while the rule has not for various reasons been so strictly adhered to as 'ould be wished, its value is gradually becoming realized so that more and more of such examinations are being made from

each clanic. At the present time the hos pltal serological laboratory is making some thing like tive or sir hundred Wassermanns a month and as the serological records are most a curately kept, data is accumulating from which most valuable combinances in Jesus van which most valuable combinances he drawn

It is the unwritten rule of the Hospital that all cases of syphilis be referred, not transferred to the Department of Syphilology for examination, advice or treatment. This is a most fortunate custom for each case is thus seen by an expert on the disease in overtion and an authoritative diagnosis is secured. In the same way the treatment is not haphazard as may be the case when not carried out by a specialist. If the report which is to follow can be considered of any value it will largely be due to the accurate and careful work of the serological laborators and the scientific nature of the work emanat ing from the Department of Syphilology of which Professor Udo J Wile is chief and to whom I tender my grateful appreciation.

It will remain for others to point out when and how the Wassermain reaction may fail as a test for lues. Undoubtedly it does fall in a negative way since it is fully recognized that an individual may have the disease and not show the reaction. Yet the test is of undoubted value when positive and if car ned out in a series of cases is a fair indication of the frequency of the disease expecially if the doubtful cases be checked up by the examinations of an extert.

Read before the American Grancelogical Security Numbers on May or

First as to the frequency of syphilis in a general hospital as revealed by the Wasser mann examination. The results in 2000 cases have been tabulated excluding patients admitted to the Department of Dermatology and the Departments of syphilology and Neurology since the inclusion of the large number of syphilities in these two services would have interfered with the purpose of the investigation which was to ascertain the frequency of syphilis in average hospital patients.

quency of syphilis in average hospital patients. In 2000 patients, there were 110 distinctly, positive Wassermanns in which the diagnosis in almost every instance was confirmed by the Department of Syphiology. Among the doubtful reactions there were 8 in which the patients were afterward proved to be syphilitic. This show that practically 6 per cent of the general run of hospital patients are syphilitic. Making illowance for the possibility that some luctus may have given negative reactions and that re-examination of the doubtful cases might have given some positives it is fair to assume that from 6 to 8 per cent of the patients in this particular hospital excluding certain clinics were syphilitic.

The percentages varied in the different series as can be seen by the following

Obstetrics and gon Medicine	-	.0,,,		Pe ug
Ophthalmology Ot larv ugology (semeral sungery	rthopedies	and.	gemt	3 7 5 0
urinary Pediatrics				4 0

The proportion of syphilities in this hospital material is on the whole rather low bullsequent reports may show decidedly higher figures more in agreement with those from other hospitals. Possibly the nature of the hospital material accounts in some measure for the low percentage of syphilis since the patients are mostly from the country districts. Be that as it may the figures are presented for consideration as a contribution to the subject under discussion.

SYPHILIS IN THE OBSTETRIC CLINIC

There were 18 undoubted cases of lues in the 381 obstetne patients examined or 47 per cent. These patients were given the Wassermann test, their hi tories taken with

special reference to syphilis and all positive and doubtful cases referred for diagno i to the Department of Syphilology

In explanation of this low percentage of syphilis among a class of patients where the ratio apparently should be high it may be said that it is probably due to the class of patients from which the material is drawn although 62 per cent of the material is made up of illegitimates the average age of the 381 patients being 23 years as a class the patients have not been unduly exposed to syphilis. They are country girls waitresses stenographers telephone operators yerr few being prostitutes or street walkers.

The laborator reports show the varying degrees of intensity of the Wassermann reaction its doubtful nature or its absence Of the 18 undoubted cases of typhilis there were 12 with 4+ one with 3+ with + and 2 with 4 reactions while in one instance although a Wassermann was not obtained on the mother the fætus showed a 3+ Wassermann and the placenta was syphilitic

HISTORY OF LUES AND CORRESPONDENCE WITH THE RESULTS OF WISSERMANN ENAMINATIONS

This is an interesting field for investigation since it shows that in the majority of instances even where particular attention is paid to the history nothing suggestive of syphilis can be found. There was a positive history of luetic infection in 8 of the 18 cases 5 gave 4+ Wassermanns 1 a 2+ while 2 were doubtful or - On the other hand where the histories were doubtful in three cases all gave 4+ Wassermanns In , cases the histories were entirely negative as to syphilitic infection but of these 4 gave 4+ re actions 2 were i + while in one case the Wassermann was not obtained the evidence of maternal syphilis being gained from an examination of the feetus and p acenta

PHYSICAL SIGNS OF SYPHILIS

In only 8 cases out of the 18 syphilities were there positive signs of lues as revealed by careful physical examination. Of these 5 gave 4+ Wassermanns 1 was 3+ while wereor doubtful. On the other hand in four cases where the results of the physical examination were doubtful all gave 4+ reactions. In 5 cases there was entire absence of signs of lies on careful physical examination although in two of these cases there were 4+ positive Wassermanns in 2 reactions were+ while it was not obtained in one case.

This is additional proof of what has long been known that in women in particular there may be few or no signs of syphilis although from other information undoubtedly the disease is present

TREATMENT DURING PREGNANCY AND ITS

The results of treatment of the syphilitic mother and the effects of such treatment upon the child prior and subsequent to birth are of especial interest to the obstetn can.

Of the 18 luctics, 14 received treatment, 7 before and 7 after labor while 4 patients refused treatment. The treatment consisted of varying doses of salvarsan and mercurs

There were 12 full term labors and 6 premature deliveries among the 18 lucties but one of the 6 patients receiving treatment before labor carned their children to full term. Of the other 6 women going to full term although in all but two instances they gave 4+ Wassermanns the other signs pointed to old infections except in one case where in fection took place at the seventh month. Of those receiving treatment with full term labora two were conceptional infections while the others were infected two to four years previously Five of the six women who miscarried received no treatment before or during pregnancy. In all except a single case where the infection was old infection occurred at the time of or very soon after concention

This is a very good showing for the treat as an aid in carrying her child to full term is concerned and shows that salvarian and mercury are well borne by the sphillitic mother. Exceptions to this statement may be found in the literature but should not deter us from instituting vigorous treatment with

both salvarsan and mercury in our pregnant syphilitic patients.

THE RESULTS OF WASSERMANN EXAMINATIONS ON NEWHOLN INFANTS

It is a routine procedure in the obstetire chare to collect blood from the unfolled cord in a test tube and send it immediately to the Serological Laboratory for examination. In no case where the maternal blood in the 38 cases examined gave a negative Wassermann reaction was the newborn infant's reaction positive. In fact only 3 of the children of the 18 luctic mothers gave positiv. Wassermann reactions at birth and these mothers received no treatment during pregnancy. Two bables mothers received no treatment during pregnancy while giving negative reactions at birth gave positive reactions later at the twelfth and lourteenth week respectively.

Thus it would seem as if treatment of the syphilit mother luring pregnancy had a favorable effect upon the child although it must not be lost aight of that the manifestations of syphilis may develop later. As it is the rule of the department that no child of a syphilitic mother with or without serological and physical manifestations of the disease shall be sunt out for adoption it will be an easy matter to ascertain the subsequent histories of the children of luctus who gave no evidence of disease when they were discharged from the maternity. This investigation on latent syphilis is now being carried on and will be reported upon later.

SYPHILIS IN THE GYNTCOLOGIC CLIVIC.

The Wassermann test was made upon 390 gynecologic patients. Nineteen of these patients gare 4+ Wassermann reactions one a 3+ while two others with less marked reactions were judged to be luctic, making a total of 22 patients among the number examined or a percentage of syphillitic patients of 50

The average age of these 22 patients was 22 years 10 were married and 6 were sangle

A definite history of syphilis was elicited in only 5 of the 22 cases while in one case it was suggestive. In only one case was a definite history of lues in the husband obtainable

The above shows the great importance and value of systematic Wassermann examinations upon gynecologic patients If such system atic examinations be not employed local le sions may be attended to surgically and by other methods of treatment but a far more important general disease will in many cases be overlooked and no attempt made to cure patients Wissermann examinations are particularly important in women since in many instances the diagnosis can only be made in this way as the local manufesta tions of the disease are far less marked in women than in men Miny cases puzzling to the gynecologist in the past because of failure to be restored to health may be ex plained at the present time, for many of them were undoubtedly cases of latent syphilis

The findings in the 2 luctic patients as reported by the Department of Syphilology are extremely interesting and show what a great aid is the Wassermann test in the

establishment of the diagnosis

There were 15 cases of latent syphilis all giving 4+ or 3+ Wassermann reactions but with few phy ical findings in most cases only a slight adenopathy. Certainly such physical signs without the aid of the Wasser mann test would have been apt to escape the notice of even the gynecologist most ex pert in general physical examination

Another interesting feature about this group of ayphilities with gynecologic con ditions was that in no patient was the diagnosis made from an inspection or palpation of the genital organs Again in no case from the material ubmitted to the pathologist was the diagnosis of syphilis made by microscopic examination Undoubtedly this would not be true of other gynecologic clinics where the lesions of recent acute syphilis predominate but these are pecial clinics and do not represent average genecologic material is also possible that future investigations of the material at our disposal in the light of what will be learned from the discussions at this meeting will enable us to recognize what heretofore has escaped our observation

SLAWARY AND CONCLUSIONS

Only by routine Wassermann tests will the obstetrician and genecologi t best serve

the interests of his patients Especially is this true in ho pital prac

tice where even careful hi tories fail to arouse suspicion of litent vibili 3 Out of oom in the unitersity

- Hospital excluding two service the propor tion of syphilities will be per cent
 - The nature of the hospital material
- will determine the percentage of lues but in the average hospital the ratio will not be iar from 8 to 10 per cent if the entire hospital pop ulation by included
- The same holds true for the proportion of syphilis in any special clinic, the percentage varying according to the nature of the mate nal
- to The percentage of lues in 381 cases in the University Maternity was 4 , as shown by the Wassermann reactions and expert physical examinations
- 7 In 18 cases of syphilis among the num ber examined only 8 gave a history of lues
- 8 In only the same number (8) were there positive physical signs of lucs
- As shown by the histories of the 18 cases there is a greater chance for the syphilitic mother treated by salvarsan and mercury to give birth to a living full term child than where no treatment be given during preg nancy
- 10 The newborn infants of the mothers so treated do not give positive Wassermann re actions although undoubtedly they syphilitic and later probably will show signs of the disease
- 11 A certain proportion of the newborn children of untreated syphilitic mothers will
- give positive Wassermanns 12 Out of 300 gynecologic patients subjected to the Wassermann test 22 or 5 6 per
- cent gave positive reactions 13 In only 5 of the 22 luetic patients was there a history of syphilis
- 14 Hence the importance of uch exam mations or a serious general disease will be overlooked and the gynecologic patient will remain uncured

THE SPECIFICITY OF THE WASSERMANN REACTION

By RUDOLPH BUHMAN MD S Lora

INCE the introduction of the Wasser mann reaction into the realm of medicine it has taken its place in the front rank of the various laboratory tests and reactions as an aid to the clinican in clearing up many of the obscure cases with which be is confronted it has received both praise and condemnation at the hands of these clinicians praise if it abled them in the diagnosis of some complicated ones, and condemnation if it did not concade with the chinical findings

The reaction is based primarily upon the Bordet-Gengou phenomenon of complement fixation that is the presence of an immune or antibody in the blood serum in confunction with the specific antigen will fix the comple The fixation of the complement is determined by the addition of corpuscles and their amboceptors. If hemolysis takes place the complement has not been fixed if however harmolysis does not occur the complement has been fixed. To illustrate the serum from a typhoid fever patient in conjunction with an emulsion of typhoid organisms fixes the complement and prevents hemolysis taking place upon the addition of corpuscles and their amboceptors.

Upon this theory Wassermann assumed that the serum from a syphilitic patient plus its antigen would likewise fix the complement However as the organisms were not then obtainable in pure culture he substituted for his antigen a watery extract from tissues rich in spirochette. By this method he obtained a fixation of the complement when the scrum of a syphilitic person was used whereas there was no such fixation when the serum was from a normal person. It was therefore assumed that the reaction was the result of a specific antigen and antibody combination may have been true as Noguchi (4) has obtained fixation of the complement with the serum from some syphilitic patients, with an antigen made from an emulsion of spirochets: in pure culture

The specificity of the reaction, however received a setback a short time later when it was shown by Levaditi Yamanouchi (1) Porges and Miere (2) Landsteiner Muller and Potal (3) Noguchi (4) and others that alcaholic extracts of normal as well as syphil litic organs had the properties of building the complement in the presence of serum from a syphiliti find idual

Although the true explanation of the nature of the reaction is lacking it is known that it does not correspond in the ordinary biological sense to that between antigen and antibody as was onginally believed. Subsequent work has tended to indicate that it is due to an interaction of lipidal substances. Future work along the lines of immunochemistry may ultimately clucidate the peculiar character of the reaction. Should such be the case, however the diagnostic value of the reaction will not thereby be increased.

From the foregoing it is obvious that the reaction is not a specific one. Now the question naturally arises. May conditions other than syphilis give a positive reaction." If one accepts the reports in the hierature then he must believe that almost all the diseases to which the human system is her will give positive reactions.

Thus positive reactions have been reported in frambours (Bruck 5 and Hoffman and Blu menthal 6) in which the etiological organism is the spirochasta pertenius. In recurrent fever and dourane Korschun and Liebfried (7) re port 50 per cent positive reactions organisms of these three diseases are very closely allied to the spirocheta pallida, which may account for the positive reactions in them. Eichelberger (8) reports positive re actions in 40 per cent of a series of scarlet fever cases Jacobovis (o) 18 out of 55 cases Weil and Braun (10) report positives in sepus cancer typhoid fever tuberculosis and disbetes Wechselman and Meier (11) Eitner (12) Jundell, Almkvist and Sandman (13) and others report positives in leprosy Boehm

(14) Reinhard (15) and Valerio (16) report positives in malaria Halbstaedter Mueller and Reiche (1,) report positives in measles vancella and pertussis Treuber (18) reports positives in lymphosarcoma Boa and Peterson (19) report 3 positives out of 60 cases of chloroform narcosis Wolfsohn (20) and Reicher (21) report positives in veronal morphine scopolamine ether narcosis Drever (22) in lead poisoning Richards (23) in diabetes with acidosis Lassen (24) in sarcoma Hesse (5) in a of 11 cases of pemphigus Sutherland and Mitra (6) in q of 50 cases of malana (3 of these were leutic) to out of 38 ct kala azar 7 out of 34 cases of leprosy Verdezzi and Urbana () report 8 positives out of 9 cases of cancer of the liver Craig (48) reports that the presence of certain strains of staphylococci and streptococci will convert negative reactions into positive one. Caan (34) re ports 3 no itives out of 85 cases of careino ma and Semon (20) Duanay (30) and 7u brycki 311 report positives in eclampsia with jaundice Serum heavily laden with bile will a caronally prevent hamolysis taking pla e without the addition of an anti-

The above reports however must be accepted with a great deal of reservation for the following reasons

The majority of these reports date back t the infancy of the reaction

2 The hability of error on account of the delicacy of the technique required in the pertermance of the reaction

A Sour knowledge of the technique has advanced the number of positives in diseases other than syphilis has gradually decreased.

4 Statistics of results obtained by other men in which it is the exception that positives are obtained in diseases other than vphilis namely Browning and McKenzie (35) Schildemandel (36) and MacCormac an J Mcroin (37)

The abundance of material furnished at the Barmard I ree Skin and Cancer H. pital gave me the apportunity to compare the variou staff the commercated above and to contribute to the question. The fillowing cases were examined. 136 cases 1 malignant diseases

53 cases of kin disea es and 90 cases of miscellaneous disea es. The original Was sermann method wa adhered to with two exceptions namely the quantity of all of the reagents was reduced one half and the watery extract antigen was replaced with alcoh lie extract. One half the original quantity was used because too much blood would be necessary since two or more antigen, were used in each care.

Hamolytic system sheep corpu des their amboceptor and complement

Sheep blood a obtained from an abatt ar immediately denbrinated washed not les than five times with tende white lution and used within twenty four in forty-eight The plan is unit rmly adhered to The variation in the density of the uspen ion is then but negligible Occas nally one will meet with cell, that are unfuly fracile and will therefore how ome hiemals a is easily determined by making up a per cent uspension of the cell in normal aline solu tion placing them in the reingerator over night and if the supernatent fluid 1 tinged some hæmoly i ha taken pla e. These are not to be used

Amboerptor The anti-heep rabbit amboerptor is used. This remain fairly constant for a period of from four to eight months if caled in small ampule, and lept con tantly in the refragerator.

Complement Fresh guinea pig serum is used. As there i more or less variation in the strength of the complement in different pigs it is preferable to use the pooled blood from several healthy animals. The complement and amboxeptor must be titrated for their re pective units before the day's work i begun.

inligens. It has been my custom to use three different antigens for the past two years. These are all prepared by a similar method as tollows.

The tissues (at tree are minced and placed in absolute alcohol (in the proportion of one gram of minced it sue to ten cubic contimeters of alcohol) incubated for a period of time (u ually four to it weeks) with frequent augitation then illicred and kept at room temperature. Antigen 1 guinea pig heart

antigen B liver from a case of congenital lues or liver from an infant antigen C a cholesterna fortified human heart prepared according to the method of Walker and Swift (42)

The antigens must be carefully titrated for their anticompliementary hemolytic and antigenic properties before they are used. The guinea pig heart and the foctal liver antigens are not as sensitive as the cholesterin fortified one. The latter is unquestionably the most sensitive and reliable of all of the antigens.

The material investigated may be divided into three groups.

TABLE L-SKIN DISEASES

Table III hows that of 69 cases, including various diseases of reacted negatively andony 5 positively. Three of the 5 positive reacting ones were leprosy of the tuberculous type. The other two were tubercular cases both of which gave a fairly definite history of lues.

INTERPRETATION OF THE REACTION

1 totakly positive reaction. Inything over 50 per cent hæmolysis should not be inter preted as a yphilitic reaction unless there is some linical evidence of the disease or a detunite history of the injection. An individual should be spared the humiliation and condemnation of being branded with this dreaded disease with no more evidence than a weakly positive reaction. On the other hand it is the duty of the physician to protect the innocent from the possibility of an infection from one who suffers from this disease There should be co-operation between the clinician and the ecrologist in all such doubt ful cases repeated Wassermann reactions should be made. If these do not clear up the case then the provocative treatment should be resorted to preferably a dose of salvarsan or ten days or two weeks of mixed treatment, which usually has the effect of producing a stronger reaction if syphilis be present.

A strong positive reaction except in very rare and easily differentiated cases is definite proof of a syphilitic infection even in the face of no other evidence of the disease

A negative reaction however is not conthe ive evidence of the absence of syphilis The reaction 1 always negative in the early primary infection usually not becoming positive until the third or fourth week cording to Craig and Nichols (35) the inges tion of a large quantity of alcohol will convert a positive into a negative reaction case of vibilithat has been under treatment may react negatively which is simply evidence that ufficient medication has been adminitered to neutralize the Wassermann body temporarily likewise the scrum from tabutics will react negatively in something like 3 per cent of cases

In so far a the practical value of the reac tion has been established the clinician should be urged to make use of same in all obscure cases

CONCLUSIONS

Theoretically the Wassermann reaction i not specific practically it is highly specific

A trong positive reaction with proper controls and accurately titrated reagents is conclusive evidence of syphilis

The diagnosis of viphilis annot be made upon a weakly positive reaction without some clinical evidence of the disease

A negative reaction does not exclude a syphilitic intection

Malignant diseases do not give positive reactions

HIGH DEGREES OF HEAT VERSUS LOW DEGREES OF HEAT IN THE TREATMENT OF CANCER OF THE UTERUS

B H I BOLDT MD FACS N WY EA

YOUR secretary has requested me to add a ten minute contribution to the symposium now before your society my part to be on high degrees of heat compared with low degrees of heat, as a nalhative treatment for advanced cancer of the uterus. Inasmuch as I but recently reported the result of my observations, I can add little to that which I published in the American Journal of Obstetrics and Diseases of Women Innuary 1016 except to say that judging from the many letters received from colleagues who have had experience my post tion is amply justified and to add that Dr F W Bancroft, of New York, has verified my position by an autoosy on a patient who had been subjected to low heat, in accordance with the technique advocated by Dr. Percy.

I do not wish to be understood as detract ing from the usefulness of low heat application On the contrary I commend it but not as the method to be used under all conditions. It should be reserved principally for a second application, after the rapid destruction has been accomplished by high hent, and the charred eschar so caused has been thrown off and for cases wherein the malignant process has so far advanced that the thorough application of high heat would endanger the bladder or rectum, despite great care to avoid injury. It may happen as a secondary result, that a slough may be caused and thus a vestcal or a feecal fistula be established. Although such fistulæ fre quently close spontaneously we know from experience, that if they do not close how difficult it is to bring about a closure by opera-

Then too the danger from secondary, hemorrhage is not less with low heat than with high heat. Indeed it is held by some to be greater when low heat is used though to judge from my own experience that position is untenable

These however would be negligible fea

tures if with low heat 410 n we could accomplish a better final result. So far there has been no evidence presented by any one who has had experience with both methods properly tired on a series of patient that showed the superiority of one over the other. It may be admitted that now and then heat has cued a patient although personally. I have not seen such as in tance.

Indeed were I to rely solely on the report of results. I hould relegate heat to the has remedies and only advise radium. But we do know that with heat properly used, and applied in properly selected cases, we have a therapeutic agent that sometimes gives remarkably good palluative effects Dr Percy who is the strong advocate of low heat makes claims for it that I have been unable to substantiate. He asserts that it has a deeper penetrating ability on the tissues and that it destroys carcinoma elements farther away from the surface to which it is applied than high degrees of heat, and hence its poten v to cure some carcinoma patients of their disease. The late Dr. Byrne to whom the medical profession is indebted for bringing the treatment of cancer of the uterus with heat into vogue, many years ago made similar claims for high degrees of heat but he was unable to convince me that it was more than an excellent palliative agent. So far as I know no proof of further efficacy has been demonstrated by Percy On the other hand the clinching facts, as shown in Dr Bancroft s case and in my case, in which autopsies were procured and a microscopical examination of the tissues made are that the cancer-cells were not destroyed to any an preciable distance from the surface of application of the low heat, certainly not farther than would have been the case with the high heat application

Dr Charles Mayo in discussing my paper on this subject at the last meeting of the Southern Surgical and Gynecological Society

Read before the American Oyucculopical Secrety Washington, Vay pré-

cited in proof of the curative power of low heat, used as Percy directs a number of instances in the Mayo clinic at Rochester of what seemed inoperable cases of utcrine cancer that subsequently became operable adding that when the uteri in these cases were examined by the pathologist he fulled to find any evidence of malignant disease in them I cannot however accept the state ment a verification of the hypothesis that low heat destroys cancer element, some ditance from the surface of heat application It can be accepted only as a personal belief based upon clinical manifestation of the individual patient. In such a case my view would be that the patient had in connection with the cancerous cervix a pure inflamma tory condition either parametriti or a local pelveoperationitis which caused more or less immobility of the uterus and that as the result of the heat treatment, the near by structures became dried out and mobility of the utern ensued but the uncer itself had not penetrated beyond the depth of the cauterization. Such clinical manifestation we also see with high heat. The inflam matory intiltration may ulsade but the carcinomatous intiltration remains prove my contention it is necessary that the operator should when the abdomen has been opened remove a part of the a picious in filtrated area in the pulst a reasonable distance away from the cervix and have it examined by a competent pathologist that shows cancer nests and the uterus becomes mobile absequently so that a rad ical operation may be done and the si ecimen then removed by a real radical operation fails to how cancer element, we are in a position to grant the alleged leep destruction f cancer element but not until such proof has been hown

I call attention to those in tances in which recovery foll wed a imple extirpation of the uterus despite the presence of some parame trial infiltration and in which after a period 1 is few m ith a re-examination fulled to

show evidence of infiltration - I myself recall two such instances

But let us pass from the theoretical and clinical test to the crucial scientific test the test being a deduction as the result of an examination of ti sue treated by low heat in the living body by which we may get evi dence which is beyond the posibility of deception This test howed beyond a scintilla of doubt that cincer nests were destroyed only in the contenzed are cand in the area immediately in contact with the cauterized surface. Even within only one millimeter of the charred zone apparently unaffected cancer nests were found. Surely high heat cannot exert a les destructive action on concercell

It is far from my intent to detrict anything from the credit of our colleague. Dr. I crey but I believe that he enthusia in his milled him as the result of his clinical experience to become imbued with unfounded hope.

Byrne although not the first man to use heat as a pall titive measure we the one to bring this treatment to a fairly extenive acceptance and was equally enthusiastic as for a time were his follower. And when I say his followers (and I am one of them) I mean those who cauterized a thoroughly as was directed by Byrne not uperficially as I have seen done time and again and yet called cauterization by the Byrne method. To speak for myself. I can say conseren

To speak for myself I can say consciention it that I obtained and am obtaining with high heat results equally as good as those obtained by Dr I ercy with low heat particularly ince I open the abdomen as insisted upon by Percy. It is my belief that if Dr I ercy will use either high or low heat according to indications he will arrive at similar conclusions especially if he subjects his work to a critical scientific analysis whenever opportunity presents itself. I be heve that the advice of our late colleague. Dr Pryor to the the internal iliaes in cases of cancer of the cervix 1 also of importance as a pulliative measure.

NOTES ON THE PAST PRESENT AND FUTURE OF GYNECOLOGY OBSTETRICS AND ABDOMINAL SURGERY

B J WESLEY BOVÉE M D FACS Wasm oro

ZOUR organization now holding its forty first annual meeting is the parent American body of the part of medicine represented by gynecology obstetrics and abdominal surgery As a national gynecolorical organization at is the pioneer of the world Composed as it is of the men most famous in America in these spheres of endeavor for the benefit of the human race its prestige is unquestioned. To be the chosen president of it should be the laudable ambition of every earnest and scientifi American worker in the specialties mentioned. It is therefore with no little pleasure and pride that I sincerely acknowledge the signal honor you conferred on me last year by elevat ing me to this important position. It is not always brilliancy that appeals to the hearts of one s confreres, as one is bound to observe in this selection. Having been for many years at least a consistent worker in and for this society I am prompted to believe the selection was due alone to that reason - Viv pride surely is pardonable when we recall the names of my very illustrious predecessors. Certainly the names of J Marson Slms T G Thomas T A Emmet, Barker Goodell. Pensice Baldy Davis, Williams, Kelly and many others who are or have been Fellows in this society will stand until the end of time as great medical genruses. Nor can I allow this opportunity to pass to pay a tribute to the parents of this society Chadwick, Munde. and J Taber Johnson all of whom have been its presidents. Though death prevents our extending the hand of fellowship to the first two the last remains to us in sterling physical and mental integrity and may honor us by his presence at this meeting. Last year on the occasion of his transfer to honorary fellow ship the society signalized its affection for him and appreciation for his services to it by sending him a very handsome tribute in the form of a well prepared letter signed by each Fellow in attendance.

In a study of the history of gynecology in America one is thrilled with pride by the remarkable strength of character portraved by the early workers McDowell Nathan Smith Peaslee the Atlees Dunlap and others passed triumphantly through the nerv furnace of acorn, hatred, and slander of communities, and even of their professional colleagues in their efforts to create a legiti mate position in medicine for the surgical removal of large ovarian tumors. In Recves memorial of Dunlap he mentions the rebuils the latter received from surgeons and even his college professor. Dunlap states re garding his first operation With a great deal of labor and care I prepared a report of the case for a Cincinnati medical journal the editor of which was my old professor of Materia Medica in the Cincinnati Medical College Dr John B Harrison The editor returned the manuscript with a note ex plaining that his reason for not publishing it was that it would encourage an unjustifiable and murderous operation which had already been tried and condemned by the profession. both in this country and Europe rebuff was from a noted surgeon who told him. You ought not to be doing such things. The Atlees in Philadelphia were condemned as murderers and butchers for doing ovariotomy and not a surgeon in New York would defend this operation when Peaslee read his paper before the New York Academy of Medicine in 1864 Kimball of Lowell Massachusetts (1855) and others were strug gling similarly to secure recognition for the surgical removal of large uterine fibroids by the abdominal route.

The work and ingenuity of Sims in the treatment of vescovaginal fistulæ will ever serve as a stimulus for the disheartened struggling against formidable agencies in various and devious avenues of study of the mysteries of the living human body, and the

T Am Gymet Sec 1854, 187 age

amelioration of its ailments. The work of his faithful pupil Bozeman in this sphere cannot but arouse admiration. Even Sims was not entirely uninfluenced by besetting disappointments and surgical failures for he was known to have become so dishuartened in his work in the South that he sold his property and arranged to embark elsewhere upon a business career. Had not the New York clothing merchant violated his contract at this juncture most likely medicine would have been deprived of the aid of this wonderful man and the human family of the benefit of his medical researches. His Drudigious mentality and great activity were again appropriated by our profession as by a providential intercession. Just why the master mind and hand of such a man cannot be spared to benefit manking indefinitely is one of the unexplained mysteries of Nature

The plastic work of the eldest Emmet and the great work of Thomas Polk and Fordyce Barker will always be appreciated. The plastic perineal surgery of J. Collins Warren the round ligament operations for the rectin cation of posterior uterine displacements associated with the names of Dudley. Mann Wylie Simpson. G. H. Noble. Andrews and others remain familiar to us all. Not to rifer to Hodge. Parvin. Meißs. and Oliver Wendell. Holmes were to slight obstetries with its other great genuses.

We must recall with American pride the impetus to unnary surgers given by Kelly who popularized direct exitoscopy and ureteral and renal exploration by its aid as well as the advanced work of several Americans in the scientific treatment of urnnary diseases. The work of Coffe and Baer in voked a great advance in the surgical treat ment of utrinary broads. To Noble by his carcful and laborious study into the complications and degenerations of these neopla ms rendered an insulable service.

I have not mentioned these great men as comprising all the talent in obstetries and genecology for surely later years have not stinted u in furni hing us with wonderful kill wirking with precise methods and securing definite and undeniable results but rather a henering myself by claiming a cer-

tun relation hip with those great men Boasting of the accomplishment of our professional progenitor and fellow worker may be producible.

be pardonable Of the splendid work of the part gynecology has not neglected the great ubject of cancer This disease as it affect women i almost limited to their reproductive organs. uterus is the organ mo t commonly invaded by it Probably Wrisberg and Montaggia were the first to recommend total hy terec tomy for its cradication. Mar hall in 178 and Langenbeck in 181 were the firt to perform this operation, though in their execu the uterus protruded from each patient. In 1814 Cutberlet recommend I by t rectomy by a special suprapulat method. In 182 Sauter of Constance for t performed vaginal hysterectomy for cancer of the uteru Recamiet in 1820 recommended a special plan of vaginal by terectomy and the following year Delpech propo ed a combined abdominal and vaginal procedure lover of medical history it is interesting to read the comments upon these coer itions made by medical writers during the next few veirs Blundell whose small book Observations on Some of the More Important Diseases of appearing in 183, is particularly interesting. Little progress was made until January 30 18,8 when Freund began per forming his radical abdominal operation after cauterizing the cervix or even amoutat ing it when large I cannot but yield to my sense of justice in passing and mention here that Freund employed as an essential feature of his procedure in 1878 the very position so well described in 1801 by Trendelenburg and that has since borne his name. It remained for our American gynecologist Emil Ries of Chicago to plan and recommend a very radical operation for cancer of the cervix which he succeeded in having performed in 1895 by the late Wertheim Ries has been an indefatigable investigator of this affection and deserves great credit. Nor can we leave the subject without alluding to the mestimable original work in the affection that was done by John G. Clark and X. O. Wurder at about the same time that Ries and Wert heim were beginning their work in Berlin

The galvanocautery as employed by John Byrne Skene and many others following their advocacy of it has been most efficacious.

Of obstetrics one must speak with considemble reserve. The untrained obstetrician has been the weak spot in our preparedness The famous teachers -- Parvan Barker and others did not to a desirable extent impress our profession with the importance of this specialty This, no doubt, was in part due to its being a heritage from the midwife who has striven to claim it as a possession later years an earnest effort has been made by a few very efficient teachers to secure to obstetrics a proper recognition. The vig orous propaganda by Williams has probably aroused the medical schools to an apprecia tion of the necessity for much better facilities for real teaching of obstetnes. From a course practically didactic with manikin demonstrations and no clinical work at has been trans formed into one clinical as well as didactic In the last few years clinical obstetrics has been a strong feature in the medical school വന്ദ്വിത The requirements of the ex emining boards of the various states reflect the appreciation of necessity of better equipment for the practice of obstetrics and has been a very strong factor in the marked improvement in obstetric training

A complaint of mefficient teaching of gyne cology in the past may be made in full justice Dealing with the disease of the female geni talia has had an inherent delicacy which has deterred the teacher from bringing students in as close relation to gynecological patients as to those suffering from diseases of other parts of the body. I submit chnical work as viewed from the amphitheaire has little superiority over didactics and students must be brought in close touch with disease in order to study it to greatest advantage

order to study it to greatest anythings of the child, abdominal surgery we may well say it remains at home with its parents. For surely it was brought into existence by gynecology and obstetrics. When we recall the fearless abdominal surgery of Lawson Tait the cholecystotomy of J Marnon Sims, and the determined effort of the latter to establish prompt laparotomy with suture of the injured viscera as the accepted treat

ment of gunshot injuries of the abdomen we at once set the relation of parent and child.

Even the first nephrectomies known to history (both fatal) that of Walcott, of Milwaukee June 4, 1861 and Spiegelberg in 1867 were done with the pre-operative diagnosis of o unan or hepatic cyst. The terst successful nephrectomy that of Simon in 1860 was done for a severed ureter com plicating an ovariotomy. The mening Sima did the first cholecystotomy Thomas operation of gastro-elytrotomy was a leader for more precise and better obstetrical abdominal surgery. Much has been written and timely regarding the unpleasant sequelæ of lanarotomies. A remarkably large proportion of patients whose abdomens had been invaded suffered from intraperatoneal ad heatons, intestinal obstruction frecal fistula aloughing ligatures, and various other unfortunate condition originating in the onerations. This was such a sad commentary upon abdominal surrery that it acted as on obstruction to the rapidity of growth of the justifiability of this variety of surgery much for abdominal surgery as placed upon a

sound basis by gynecology and obstetrics. As yet the general surgeon had little to do with abdominal surgery. Vor was his at tention directed practically to it until the specialists mentioned had ripened and prom mently and enthusiastically praised this great tield of survey. Its early days without general angethesia or asepsis must be reviewed by us with shuddering amazement Many of us have seen it without the latter when it seemed disheartening To Crawford W Long who like Sims, had been an obscure village physician and to the creators of clean surgery we owe no small obligation. It has been markedly developed during the last thirty five years so that now no portion of the lower half of the torso has any unknown parts. Even the suprarenal body is being resected for quite definite indications.

It would be unpardonable not to give due credit to bacterology for its powerful aid in arriving at the intelligent treatment of in fections found in the pelvis and the abdomen One is led to wonder at the lateness of this correlation of bacterology with evencic and abdominal surgery. Lven as late as Decem ber 1879 in a debate in which many of the leading surgeons of London participated Mr Timothy Holmes was able to say convincing proof of the germ theory as applied to living tissue and living phenomena has as far as I know yet been offered was not until 1881 that the observations of Ogston on the relations of micro-organisms to surgical disca es were published not until the publication of Rosenbach in 1884, and of Passet in 1885 were the vari eties and natural history of the common or ganisms of suppuration fully described and their identity established. These had to be preceded by the epoch making researches of Koch on staining methods and culture media Since then this branch of medicine has at tained by wonderful strides a position of vast importance in the three great helds of medicine under consideration

During the forty years existence of this society there have been times when it has seemed the problems of gynecology and obstetrics were practically all solved that nothing new was to be learned and that solely practical application of known facts was to be their future. This was indeed a gloomy view for the generation that marks no ad vance over the work of the preceding one is practically dead. In the field of investigation of the better cementing of the brother hood of man and of the uplifting of the human family - in all these - advances must be constant In fact the very existence of such specialties was thought to be reopardized The mechanical part of gynecology sur gery was being largely taken up by the general surgeon who giving little heed to the real foundation of gynecology - that of the study of womanlind-perhaps thought that operations constituted the whole field of this branch of medicine The family physician entering the practice of his profession very poorly trained in the science and practice of obstetrics soon secured a rather large obstetric clientele absolutely by propinquity He promptly learned that women served in time of such suffering were deeply appre ciative and retained his services for other profes ional neces ities. Such conditions naturally lent themselves to the creation in many minds even in some great one of distinct tear of extinction of these two great sister specialties in our science. And yet the Jeopardy was more threatening from other directions. Ominous clouds pa sed in review. In many medical colleges generally no longer regarded as an important peculity was obliged to a unit in incignition rolling the work of the chair of surgery. In others it was combined with better in one chair. While recognizing both peculitie this plan robbed both of their dignity and presture.

Another effort to terminate the exitenof at least one of these branches of science was that of the section on surgery of the American Medical Association at a meeting a few years ago to have it sphere extended to include gynerology and abdominal sur-It failed however and at a subsequent meeting of the association abdominal surgers was added to the work of the section on obstetrics and diseases of women. I under stand an amicable adjustment has been made putting abdominal surgery in both of the sections mentioned. The situation of gyne cology and obstetrics may now be regarded is stable. I believe no fear need exist of loss of recognition of either. Both are very healthy adults and not to be regarded as infant in dustries needing fostering care. No distinct pause in their development has occurred since the organization of this society ing of the medical student in gynecology is on a splendid plane. The graduating student is far more proficient in gynecology today than was the general physician of several years experience a hort time since. The care fully prepared case histories - prepared by students under efficient supervision - the thorough laboratory investigations and opportunity for carefully supervised physical examinations bring the students to a basis for logical diagnosis - the paramount ne cessity for correct treatment. The clinical teacher who frequently states something is wrong in this abdomen and I will open it and then make the diagnosis endangers hi reputation

In the teaching institutions the same plan

of instruction in obstetrics obtains to a conaiderable degree. Both obstetrics and gynecology are gaining in this respect and while we do not expect marvelously rapid transformation in such matters owing to the marked changes in hospital construction and regime necessary thereto nevertheless a sense of pleasure has come to the teachers in these branches of mediane from the progress of the last few vers.

In abdominal surgery the dread of dire results from sensis umorance shock hæmor rhage and several other former causes of needless mortality has nearly vanished While problems in this field of endeavor remain unsolved, diseases of the abdomen are much better understood than formerly Various aids are now being employed to assist in the diagnosis or treatment of pelvic and abdominal diseases and I dare say they will have notable extensions. The roentgen ray has greatly assisted in the discovery and location of adhesions, neoplasms, ulcers and stases of the stomach and intestine determin ing the presence or absence of hillsry renal. and ureteral calculi and indeed with the preteral catheter is an extremely reliable agent for determining whether urinary calculabove the bladder exist. We are justified in beli ving it will prove of great value in diagnosing pregnancy and various abdominal and pelvic tumors. Laboratory findings in buetic and Neisserean tubercular and other infections though of great importance, must and will assume a still greater rôle in our arrencies. I feel sure that even improvements will be made in more careful investigation of nationts histories to determine the time for operation as well as in the technique to be followed. Already the surgeon is cautious in radically invading infectious areas often delaying with advantage when the less skillful would fairly plunge into a surgical operation. F F Simpson has recommended marked delay even months, for radical operations in infections in and about the uterine appendages. The value of this plan can scarcely be questioned and its universal acceptance may be expected in the treatment of patients who can afford the extra time this requires. It is another feature in the conservative

practice that goes with greater knowledge. In ectopic pregnancy his advocacy of delayed operation has been quite universally heeded.

The subject of displacement of the uterus from time immemorial has been a fruitful one for lively and even bitter discussion. Careful study 1 the forces maintaining the position of that origin are gradually lessening the differences of the past in this respect and we may reasonably hope for full accord in it. Pelvic non puerperal infections are steadily losing their terrors and we may look for them to be practically removed from the class of highly dangerous diseases. This will be largely due to the recognition of the superiority of dependent drainage and conservation in their radical treatment.

The treatment of cancer of the uterine cervix continues to receive the very earnest attention of gynecologists and special ac tivity in the gen ral subject of cancer during the past three years has been enthusiastically aided by this society. Thus far the cause of can er has not been found and no doubt this must be discovered before we may reasonably expect to gain a mastery over this dreadful disease. Its behavior as influenced by m dium and long-continued, alightly elevated temperature as advocated by Percy is of interest. The use of certain rays from radium seems to retard its progress and perhaps com pletely destroy it while other rays from it are thought to induce the disease. If the latter be a fact we may well refuse to believe, for the present, that cancer is of microbic nature. Even the Percy method emphasizes this doubt for it should stimulate microble ac tivity yet its retarding influence on the prog ress of cancer of the cervix is attested by many careful and rehable observers. But nuther of these two agents can be regarded as a specific for this disease for they are both notably limited in their radius of action Whether radium has deeper penetrating power as a cancer destroyer than the Percy heating method is a matter of doubt and the cases reported by Boldt throw grave doubt on the penetrating power of Percy's method used for this purpose. This latter method is based upon the application of a low elevation of heat to the involved tissues. And vet

for this purpose is employed an instrument so hot that it has constantly to be moved to prevent overheating and the heat is gauged principally by the sense of touch through the utering wall which varies greatly in individuals. If this method is proved a specific against the active agent of cancer is it not to be the sole agency in the treatment and cure of cancer in the breast bladder vagina vulva and rectum? If it has a positive specificity for two inches then no part of the human body will be maccessible to its beneficent influence

It would appear then that our hope in cancer of the uterus continues to consist of surgery as early as possible universal educa tion on this subject the employment of radium and high or higher temperatures and unremitting search for the true etiology of it Radium offers benefit to other forms of neoplasms particularly to the bleeding uterine tibroid according to several credible observers. Nevertheless it is vet but an empiric agent not available to more than a very small percentage of patients suffering from the many conditions in which it is extolled and not without its evil effects, such as corresion of While we may believe enthusiastic faith has had much far too much to do with the reported results of radium application we cannot fail to recognize that this agency when properly harnessed has great possibil ities in the treatment of pathological conditions I believe it is deserving of being absolutely divorced from charlatanry and com mercialism. Its exploitation has been un fortunate

In obstetric a nearly parallel situation is found in the aid and sympathy several prom ment workers and teachers have afforded the ensational use of the various alkaloids of hyosevamus and opium under the alluring name of twilight leep. In the sweeping march over the continents of this dangerous method the professional and moral fibers of even the flower of the obstetric world have been challenged. It has nearly equaled the tales of the French revolution. It is he heved the danger of this awful flood has passed and the conscientious and competent b tetrician may n w come down from his

Mount Ararat and pursue the even tenor of his way Probably humanity has been benefited by this visitation only to the ex tent that it has prompted us to tal a stock of our methods and even of our humanene s and has appealed perhaps not unnecessarily to still greater concern for the suffering of our patients. The outcome of it i substitutes for opium and hyo cyamus are now employed Probably the open mind is now predicting that at no distant date twi light sleep will rarely be recalled to memory and nitrous oxide and oxygen inhalation during labor will be given an enduring place in the obstetric régime

It is highly probable that cre-arean section will be given a wider field of application The vulnerability of tissues of women cer tainly of American women will be fully recognized and they will not be subjected to unreasonable and unbearable obstetric strain and avoidable infant mortality greater advance in teaching obstetrics may be expected than has been obtained Largely to J Whitridge Williams should we attribute

such improvement

In abdominal and pelvic surgery at its present stage of development probaby no more important matter is before us than the prevention and correction of interperitoneal adhesions A propaganda on this subject should result in untold lessening of human suffering Very likely an active educational campaign would greatly lessen the evil of post-operative adhesions. The finding of large areas of adhesions in the abdomens of patients who have been previously subjected to laparotomy for simple or clean conditions is far too common to escape the attention of the careful abdominal surgeon is it always the tyro that unnecessarily violates the parietal and visceral peritoneum by undue handling suturing etc. Various materials have been extolled as prophylactics against post operative adhesions. I will not tax your time by enumerating them but will garded by some of America's greatest abdom inal surgeons I feel I must severely enticize One to three years after I had smeared it over denuded peritoneal area. I have removed from the abdomens of patients encysted masses of vaseline having diameters up to one inch and have found adhesions were very extensiv. In some places these capsules of vaseline formed a dense rigid connecting structure between several lo pe of intestines. Acting upon the theory that

before a fibrous exudate can form in the pentoneal cavity with its resultant plastic applutination there must be the liberation of that hypothetical ferment, thrombokinase its activation of prothrombin in the presence of calcium and the production of thrombin Saxon Pope experimented on sixty rabbits and published his work in January 1014 These experiments were made with many different materials and he concluded from this work that a solution of 2 per cent sodium citrate in a 2 per cent solution of sodium chloride was the best remedy. His faith in his conclusions is proved by his reporting in February 1016 the results of the employ ment of this hypertonic solution in 400 abdominal operations in the University of California Hospital. Walker and Ferguson. doing 104 operations on 63 rabbits, found 3 per cent of the citrate in 1 per cent of sodium chlonde solution was the most satisfactory giving complete success in 70 5 per cent and 88 2 per cent partial success Certainly such results merit our attention. In the presence of sepsis or deep or wide destruction of tissue it is not claimed these hypertonic solutions can be regarded as infallible but even here they are of use. In my personal experiences with the 3 per cent solution of the citrate in quantities of 200 to 300 cubic centimeters considerable shock has been noted Among the questions that arise in our minds are

- If it gives absolute success in ,0.5 per cent in mild peritoneal traumatusm can its use be extended to success in such severer peritoneal injuries as separated adhesions?
- 2 How long must it be in contact with the area to be of highest efficiency?
- 3 What is the duration of its activity?
 4. Can it be used efficiently in gauze covering large areas of pentoneal denuda

Ann Sury Plule pee, br., an. Ann, Sury Plule 1924, lant, 203. Ann ary Plule 926 lunt, 298 tions and brought out through the abdominal wall?

If these questions are to be later answered satisfactorily to us then we will have positively mastered this much dreaded and dangerous complication—peritoneal adhesions

Coffee has recently invited attention to his rubber offerdam brought through the abdominal opening used in separating pelvic adhesions in a ute attacks of adnexal in fections. Though he specifically claims no herma foll we this prolonged abdominal drainage I fear that claim will not tempt many to use this method of dealing with such conditions. I believe the paraffin-steame gauze recommended by Fisher used as a dramage material for pelvic adhesions and conducted through the vagana will be found very satisfa tory. While I have not at tempted to be a seer yet I have been so im pressed by some of these efforts to lessen the dreadful peritoneal adhesions that I have been emboldened to risk turing you with this re hearsal

We are at great best for lack of knowledge of the influence of luctic infection on the pathological conditions we as specialists must treat. In the past the degree of precision in diagnosis of this variety of infection has been so slight that we have not been able to associate with it observed legions to the degree of certainty that the Wassermann reaction now The routine blood examination reveals a starthing frequence amounting almost to regularity of the positive Wassermann which quite reliably indicates the presence of lues It is to be hoped the attention given to this subject at this meeting of our society will have the much needed stimulating influence on the profession in general necessary to a due appreciation of the momentous importance of recognition of lues in obstetrics and gyne cology

Surely there are very many grave problems to be solved in the fields of endexor you represent but I am unboundedly confident the society will in the future maintain in that work the prestige that has come from the high character of work It has performed

Jan M im seif, br ope.

EPIPLOITIS FOLLOWING HERNIOTOMY

BY WILLIAM HESSERT M.D. CAUS CHUA

ISEASES of the omentum are relatively uncommon and literature on the subject is scant, especially in Engli h language Omental diseases are either tumors or inflammations The former include careinoma sarcoma lym phangioma cyst and teratomata inflammations are divided into two groups which include fir t the cases that occur po t operatively and second those not preceded by operation. Hermotomy is the operation most frequently c accrned in the first group and ince heation of the omentum is done in only a smill min rity of hermia operation it fellow that epipleitis as a complication i likely to be uncommon. Some operators with large experience in herma work have never encountered it

The most recent publication on the ubject of inflammators tumor of the omentum is by L. I cterhanwahr? This author has collected 44 cases 36 of which had been preceded by operation mostly hermotomies. Lucas Championière observed two cases of epiploitis among 275 operations for herma Duboi one in 300 cases, and Tuffier one in 600 cases.

The French literature contains the fir treference to this subject in 1802 by Luci Championière followed by Reynier in 1803 Forgue in 1806 and later by Boeckel Menier. Morestin Le Dentu and others Schnitz ler's article in 1900 was the first to appear in Cerman Cumston and Humann are among the few who have written on the ubject in this country.

American writers in herina scarely mention the possibility of apploitis following lighton of the omentum. While it is true that apploitis is a raid complication in this country due to the general use of absorbable lighture material yet the matter is of more than academic interest and should be familiar to every surgeon. The fact that two case eccurred within a hort period in the writer.

practice suggets the left that more cases would be diagnosed were there a better understanding of the subject

The case hat ones which a llow allustrate the cute and he mattyle at the liserse

The ibdominal pain become general and all the ympt m were interacted. Who ends the riter ath tweltth day of the fiscase the in his niof the patient was desperate. He present I the type I picture of gene il peritonitis and it was input I to de termin v bether any relation exited between the peritoriti and the fire high miot my

The aldomen a mm slat Is opened by means of a left rectus meason on a lc. I with the unbils us. The peritonical casity was full of puss under high tension the fluid vas turbal and flaks and the bowels were covered with exudited. The ligated pedid to fit the or attum was turbal in the upper I fit quadratard of the abdomen. It was a miss the size of a lemon cover d by eau late, and saturated with puss. The adhesions to the abdominal all were madly separated and it was seen that the tumor was losely attached to the trains recolon. The catiguity light ture was still intact. A hurried a minimation revealed no lesion of bowes I lad let or where organically have been also also the properties of the catiguity was done further than frain but the patient ded twenty four hour after the catiguity.

This infection of the peritoneal civity could have been introduced in no other way than by the retracting omental stump. The omentum became contaminated during the progress of the operation and the pedicle proved a favorable medium for bacterial growth. The catigut was not at fault, for the same material was employed in the repair of the hermia, which healed per primam.

CASE 2 V man 40 ves of sige had a large right inguinal hernia which as operat don and a large piece of om ntum was removed by the aid of several catgut hig tures. The wound healed without in tection and the patient if it the hospital at the end of two weeks. After a free interval of about two weeks he begin to suffe "upus abd minal pains. Two weeks late he consulted the writer and complained if general misiase anor via const-patio pains on the right aid if the abd men and awelline bout the level of the navel.

Examination of the site of operation we negative
the herda had healed perfectly. The bodomen
was slightly distended, and the mixels on the right
side are somewhat rigid. The night of the
multilities a mass could be felt whith we about
four inches in diamete and fairly well circumscribed.
It was sensitive to pressure, and did not me with
respiration. There was dullness, almost flatness
on percursion but a zoop of tyropany separated.

this area from the liver.
There was nothing bout the findings to suggest
mvol ement of the liver or kidney and the mass
was rather highe up it he abd men than the or

dinary appendiced abscess. There was an evening rise i temperature to o and a leucocyte count of ,000. The urine was negative and further physlcal examination as negative. These findings—th

the hirrory abould have suggested the diagnoses. The abdonne was opened through a right extus incision directly over the tumor which was found directly on the bolomial will. The adhesio could be readily separated and the mass freed from the will and underlying bovets! Upon delivers the mass was found to consist of inflamed omental tierne. Almost all that was left of the omentum was involved, there remaining only a small bridge of healthy times where it was attached to the transverse colon. This was fortunate, fo it permitted easy ligation and removal of the whole tumor. The inguital region was found on examination from the inside t be perfectly normal. The patient re-

covered from the operation and emained well. The tasie removed was hard and dense, being composed of inbrois and fatty tissue, with prepared to the former. In the center of the mass several small abscesses were discovered from which scaphylococcus sureus was grown. No trace of the hightures could be discovered. This case fillustrates the most commonly between type of epipolish namely, the subscrite variety. It differs only from the ordinary in that catigut was used instead of the more notorous offender—ally While number of the reported cases has recovered

apontaneously th findings in this case preclude the

A number of types or varieties of epiploits are described by various authors, but the classification of Peterhanwahr seems to be the best.

- 1 Post operative variety (a) Simple in flammators hyperplastic type (b) Suppurative epiploitis.
- 2 Extension from neighboring argans, not following operation

Sauget describes three varieties as follows

(a) Epiploitis plastica simplex (b) Epiploitis plastica with adhesion (c) Epiploitis

purulenta

The variety most commonly observed is the sample inflammat. In hyperplastic. The free interval after operation before the onset of symptoms is variously reported at five days to three years. In the majority of cases howe er it will average three to four vecks.

The type of inflammation which develops in the given case depends upon the virulence of the intection or the degree of mechanical unitation In the very acute cases, of which an example is reported in this paper the acutely inflamed omentum is but part of a general pentomitis. A the process becomes more bronic the inflammators products become more organized and fibrous. The mass may look like a thirolipoma and on sec tion one or more abscesses are usually found with the ligature as a nucleus. Adhesions to the abdominal wall are most constant, and at times large abscesses have developed which were opened by the surgeon or gained a spontaneous exit. Sinuses have form and persisted due to the presence of masses of silk

There remains finally to be mentioned the bordy growing thronic form which so much resembles a malignant tumor that diagnostic errors are almost inevitable. The structure of the mass is so dense and fibrous that this together with the absence of pus simulates the gross appearance of malignancy closely it is the opinion of many that the mechanical irritation alone of the allk without any accompanying infection, is a public of developing the large fibrous growths which have been

The factors primarily involved in the development of epiploitis are the following

- The ligature material
 The manner of ligation
 - The condition of the omentum at the
- point of ligation.
 - 4. Infection.
- r The ligature material In about 90 per cent of the reported cases the material used was heavy silk (Reynier Monod

Guinard Braun) In a mall percentage of the cases other material such as catgut or kans 1700 tend in was employed. Silk alone without added infection has been known to stimulate the development of enormous throu masses. The explaned by Hollander on the theory that while the lighture may have been drawn turbtly enough on the pedicle to secure hamostisis it did not produce necro is and the bit of living tissue in the stump was tirred into tumor like growth by the irritation of the silk. I am inclined to the belief that there is an element of infection in all of these cases. Virulent infection will result in any of the acute types of sensis while a mild infection may exentually become sterile or result in sinus formation. sinuses will not close until the offending silk is eliminated. Absorbable ligatures when infected provoke the same disastrous results as silk. The absorbability of the material when sterile precludes the possibility of any late irritative effect

- 2 The manner of ligation has much to do with the occurrence of epiploitis. The case records show with few exceptions that the omentum was ligated either on masse or with a figure-of eight ligature. This bunching of the omentum into one ligature has been a fruitful source of trouble.
- 3 The condition of the omentum at the point of ligation has had much to do in con tributing to a bad result. Thus if section is made through diseased tissue the result of chronic inflammation as is so frequently observed on old or incarcerated hermas the retracted pedicle becomes a source of trouble Reviner. Roche. Bocckel, and others report cases of this hind in which silk was used.
- 4 Intection It seems probable that in fection is the most important factor acting either alone or in conjunction with any of the other predisposing causes. That the trritation which results in the formation of large tumor like masses is entirely mechanical is open to question. How often do we see salk when sterile heal in the tissues without cile when the control of the true in gany traction whether. When large thorous masses develop we have bacterial irritation added to the stimulu, of the foreign booly, the lik lighture. It is contexable body the lik lighture.

that a low grade of infection after prixium, its effect might become tende and culture taken from the ilk would how no growth thu lending upport to the mechanial theory.

VALUE

In the very leafer ease the symptom are a few day latter pertinon and on it of the useful ground on it of the building of in it the intesting within the abdomen leading with general apparative peritority. In time, the process may become leadined with above 1 primition.

By far the majority of the cases run a jubaction course. It tim, for month, or even years. The free interval after operation is generally of four to eight week, duration but cases are on record in which two to three years clapsed before the onset of symptom.

Lain is one of the fir t and most con tant symptoms. It may at first be in any portion of the abdomen depending on the location of the inflammation. Frequently it is in the upper abdomen and a aggravated by deep breathing coughing or tight clothing sociated with the pain there is a ually a rise of temperature with all its attending vmp-There may be an absence of urns pointing to any special organ and in some cases the symptoms all subside and the patient gradually makes a spontaneous recovery. More often the disease continues progressive with finally all the signs of a localized abscess in the abdomen manifest The pus in such cases may rupture into the bowel or succeed in burrowing through the abdominal wall

In the type of cases that develop slowly and insidously with vague and ill-defined symptoms there is great resemblance to the clinical course of a cancer. The presence of a palpa ble mass is further suggestive of malignance. In doubtful cases the abdomen has been opened and even then the operator is in doubt whether the tumor is a carenioma surcoma or of inflammatory origin.

DIAGNOSIS

In every case of a hermiotomy where ab dominal symptoms supervene the possibility of epiplotis must be considered. It is very likely that there have been many cases which

have not been recognized or have been incorrectly interpreted because epiploitis in this connection has received but little at Diagnosis is suggested by the occurrence of pain associated with the de velopment of a mass in the abdomen. The tumor is usually on the same side as the herni otomy on a level with or above the umbfixtus The tumor has been but rarely seen in the nelvis or inguinal region. The tumor varies in size but has been known to grow very large It is tender on palpation and is usually fixed to the abdominal wall so that it does not move with respiration. There is usually duliness or flatness on percussion as the intestines are beneath the mass

In differential diagnosis one must consider cholecystitus subacute appendicitis, chronic perforation of the stomach foreign body (such as a gauge sponge) diverticulities of the alemost and pancreatitis.

TRUATMENT

According to Braun the development of an inflammator, tumor of the omentum after herniotomy does not necessarily demand on eration for a fair proportion of such cases recovers under expectant treatment. It is fair to assume, however that the diagnosis in some of the recovered cases might be open to some question

The most radical view relative to treatment was expressed by Reynier one of the early writers, who advised extirpation of the tumor as though it were malignant.

The practical lesson to be learned is that we should be familiar with epiploitis, as it may complicate recovery after a herniotomy and adopt the measures necessary for prevention These are in fact elementary and include first a faultless operative technique, both asentic and mechanical. There should, above all be an avoidance of rough handling of tissues. I ortions of the omentum should not be removed at all during the performance of a herma operation unless there is a valid indication. If resection must be made, then absorbable suture material of as small a size as possible should be employed. The vessels in the omentum should be tied with many tine ligatures, and the use of en masse or figure-of eight ligatures should not be con sidered Section should always be made through healthy omental tissue never allow ing any diseased tissue to also back into the nbdominal cavity

After the diagnosis of epiploitis has been made the decision for operative interference rests with the judgment of the surgeon. The acuteness of the symptoms and the progress of the disease would be determining factors. Under ordinary conditions no harm can follow an exploratory incision. It is best to remove the inflammatory mass completely if possible If owing to adhesions and abscess formation. removal is impossible then there should be thorough drainage

In the event of intestinal obstruction caused by an ld tibrous inflammatory mass, it may be necessary to resect or shortcurruit the box el

THE TRANSPLANTATION OF THE ARTICULAR END OF BONE INCLUDING THE EPIPHYSEAL CARTILACE LINE

By S. L. HAAS M.D. SAN FRANCISCO

From the P thological Labor tory and the S - cil P thological Enhoratory of Lehand Stanford J - Universit - School of M da ne

In a previous paper entitled. The 1x permental and transplantation of the Epiphysis the effect of transplantation on the longitudinal growth of bone has been considered by the author (1). The results of those experiments show that the longitudinal growth ceases after transplant tion of the epiphysical cartilize line whether by itself or with a neighboring piece of epiphyseal or diaphysical bone. In the present article a description of the macroscopic and microscopic changes occurring in the various components of such a transplant will be given.

Thus it becomes necessary to consider the changes occurring in the articular cartilage the marrow and the trabecule of the epiphysis the epiphysial cartilage line the nitrow and the trabecule of the diaphysis and the cortical bone. Normally there are certain constructive and destructive changes taking place in a growing bene but with the additional influences of tran plantation the complexity of the study is considerably mereased.

In order to under tand clearly the changes that tal eplace it will be advisable to describe minutely the structure of the epiphy seal and of a growing and developing bone because certain terms not given in the u ual histological descriptions are employed in the text and also because it is necessary to express in definite defining terms what is understood as epiphy i epiphyseal cartilage line and metriphy is which are so often very loosely employed.

Vormal epiphysis In the very early periods of bone development the epiphysis is entirely cartilaginou. With the appear ance of the center of ossification there is a gradual disappearance of the cartilage until ends a hell remains surrounding the cancel lous epiphysical bone and marrow (Fig. 7). The cartilage at one end persists to form the articular exitiage, while that at the inper-

boundary forms a part of the epiphyseal car tilage line. The part of the epiphy-cal line toward the comby a will be designated as the epiphy-eal o itying cirtiliginou layer (Fig. 1) It can its of hyaline cirtilage with irregularly scittered nuclei and from its epiphyscal side o itying bud t cirtilage extend into the couphy i In the older animal the part of the hell of cirtilize con necting the articular cartilage with the comply seal cartilitie line underlines complete os incation so that the articular cartilage is no longer found to be inserted into the epiphy seal line. The remainder of the epiphyseal cartilage line is composed of columns of cartilage-cells, the nuclei of which are flat and heavily stained near the comby-seal oscilying cartilage layer but gradually become round and larger on nearing the metaphysis until they finally are of a vencular structure with a surrounding light strunging protoplasm These large vesicular cells form the boundary between the epiphysis and the metaphysis and anally become a part of the latter. It is by the proliferation of the curtilage-cells of the epiphyseal cartilage line that the longitudinal growth of bone is maintained. The exact process of this procedure will not be con idered at present

Normal nataphysis. The metaphysis is made up of osteoid tissue in which there are numerous vascular loops. I ytending into the diaphysis are long irregular columns of cartilaginous matrix which are in various stages of ossilication, from partial at their beginning in the metaphysis to complete at their ending in the diaphysis. This will be designated as the metaphyseal ossifying cartilaginous layer (Fig. 1). There is a rich vascular marrow between these columns of ossilving cartilage.

The material for this report was obtained from seventy in experiments on dogs mostly in the early growing period. All of the opera

tions were performed under general ether an mathema during which the usual ascott measures were employed. At the con lusion of the experiment the foot was protected by a light plaster-of Paris dressing which wa allowed to remain from fourteen to twenty one days, the animal in the meantime having full freedom. At the conclusion of the periment all of the metacarpal and muta taraul bones were measured in order to de termine the amount of growth From a large senes of measurements in normal animals it was found that the two central bones of the metacarpal or metatarsal region of the same and of the opposite side, are all practically of equal length (Fig 2) This affords a stand ard of comparison and allows an easy method of determining the amount of actual growth As the metacarpals and metatarsals possess but one epiphysis attuated at the distal end of the bone any change in growth that takes place can only be caused by proliferation from that particular epiphyseal cartilage line

Roontgenograms were taken of the feet in many instances. Part of the specimen was preserved in Kaiserling's solution and part used for microscopical study. The tissue for microscopical examination was fixed in Orth's fitted embedded in celloidin and the cut sections stained with harmotoxylin and eodin or Van Gieson's stain. Fifty-eight of the more important experiments are described in detail

REIMPLANTATION OF EPIPHYSEAL CARTILAGE

Method The distal end of the bone is exposed until the epiphyseal cartilage line is visible. By means of a charp scalped a cross section of the bone in the region of the epiphyseal cartilage line including an adjoining piece of the diaphysus and the epiphysus is excised and immediately reimplanted. The width of such a section is about 0.4 cm. The piece is anchored in place by an \(^1\) shaped sature over the dorsal surface and the wound closed in layers. At the termination of the experiment the adminal is killed by means of gas.

Experime t Duratio 4 days. Dog 24 14 ge 1 months.

In these experiment the ord best elected be part of he beam.

the was not complicated.

Macroscopical description. The healing is nor mai. There is no growth of either normal or oper ated bones. The reunplanted segment is in contact with the host of its distal but of at its provincial.

Merca opical description. The atticular cartilages ppears now mid. The marror of the epiphysis shi as definit evidence of degeneration in both the recomplanted peece and u the host. The trabecular of the posperospecies and other host computed and of the bone-computed and appear to be under going early degeneration. The epiphysical cartilages have presents a rather normal appearance saide from

increase in width. The metaphysis shows a rural arrangement of the ossilying cartilage olumns but there is some lack of nuclear staining. The intervening marrow is necroit. The marrow i the disphysical part of the transplanted segment is adeepoing necrois. The nucled of the trahecule of the disphysical part of the running and trahecule of the disphysis tain faintly and appear to be degreerating. The standard to lector in clear staining. The element of the control of

age 3 months

M croscopical description. The healing is nor
mal. There is no growth of the normal or the oper
sited bon b t there is a considerable thickening in

the region of the implanted cartilage.

Mixrox opical description The articular carti lage became displaced following the operation so that the outer surface is turned inward allowing a bnormal penetration of hirous tiesu int articular cartilage. The marrow of the epiphysis with the exception of small area on the dorsal car the epiphyseal cartilage line is replaced by y ung onnective timue i which are some fat rells. The trabeculæ of the epiphysis are for the greater part made p of a homogeneous non-cellu-Som of the trabecule especially near the epiphyseal cartilage line on the dorsal surface. begin t show problemation of new openous thesi bout their periphery. The enaphysical cartillage line is markedly changed only a band of carrilaginous these remains, which corresponds to the epiphyseal omifying cartiloge layer. The cartilage olumns are entirely replaced by fibrous and vascular timue The metaphyseal ossilying cartl laginous zone is replaced by ew formed osteold tissue. In the diaphyseal marrow there is a slight increase of polymorpho uclear cells. The trabecular and cortex ha a normal appearance

Experiment 3 Duration 3 days Dog 23 3L, go 1/2 months

At croscopical description of good healing is present The growth of the perated bone is a cm while the normal is of the many of the epithysis is the pressure smooth and the marrow of the epithysis is the formal. The epithysis is the control of the marrow of the epithysis is the control of the many of the line and the marrow of the first in the control of the line and a broad band of whit there is the region of the metaphysis. The line is

of umon are till distinct. The remain ler of the

bone appears normal Microscorical description. The artifular ortil age is normal in arrearing a rile from a light fibrous diposit in the out relay r of the perichon drium. The marrow of the epit hysis distal to the transplant is of normal ppearance while that t the tran il nt i necroti and fibr u ex ept for a small area on the direal lile nor the epiphy eal cartilage line. The trabe ulre of the coulds a how a considerable am unt of osteral pr lit ration about the homogeneou c ntral part (fig 3 The epi physeal artilage In is almost loubly the normal A dist n tlne of la ag i seen in the row of columnar artil ge which livides them trans versely into a proximal two-thirds and a distal one rrespond to the lite treak third. The remnanter of the transplant and host piper in mail.

Conclus on on Keimplants ion of the Epiphs seal Cartilage Line

In general the changes are contined to the reimplanted it use. The earliest changes are seen in the marrow tis use where there appears to be a necrosis of the greater part even as early as the fourth day. The mar row spaces at 1, and days are hilled with a hibrous connective tissue but at a latter period a further differentiation takes place and new marrow is formed. In these experiments on account of the close proximity of the normal tissues of the host at it is impossible to determine the origin of the regenerated tissue.

The first evidence of degeneration of the epiphs cal cartilage line is seen at 23 days and appears as a cleavage line extending through the cartilage columns so as to divide it into a proximal two-thirds and a distal one third Later a progressive degeneration of the epiphs cal cartilage line occur as is shown by the 44-day and b3-day experiment, there being almost a complete disappearance

f the cartilage in the latter experiment

The trabeculæ undergo degenerative changes as early as 4 day and at 23 day there is regeneration from the periphery which is practically complete at 44 day.

The transplant heals in place so that at 44 days there is no evidence of the line of union.

AUTOTRANSPLANTATION OF THE EPIPHYSEAL

Method In this set of experiments a cross section of bone from the region of the epiphyscal cartilage line, including a piece of adjoining epiphyscal and disphyscal bone is transferred to take the place of a similar section from a corresponding bone of the opposite foot.

Experiment 6 Duration 23 days Dog 3 3R, age 16 months

age 14 mouths. Macrocopean description. There is good healing The increase in length of the operated bone is can while the normal bone is increased to 6 cm. The bone is broader than the normal especially at the epiphyseal end. The articular cartilage is mooth The lines of union are just valide. The epiphyseal cartilage line is rather irregular and has lost is normal gelatinous appearance. Just provingal the epiphyseal cartilage line is a band of tessue 16 white color and the bone in that region is denser than normal.

Microscopical description. The arricular cartilage is of normal structure except for a small defect at one place o the surface. The marrow of the non-transplanted part of the epiphysis is while that of the transplanted pace contains scattered areas of necrotic marrow. The trabecular of the non-transplanted part of the epiphysis are normal while those of the transplanted portion are poorly stained, especially toward their centers. The epiphyseal cartilage line is divided into a proximal two-thirds and distal one-third on ac count of the degeneration of the thrue in that region (Fig 5) The parts on either side of the cleavage li present fairly normal appearance. The cartilage beneath the perachondrium is in a stat of active development. In the met physis the provisional ossifying cartilage col mas have a rather irregular ppearance and there is a fibrous and necrotic change of the marrow. The line of union of the diaphysis is quite distinct especially near the periosteum where there is a considerable amount of callus. There is an increase of leucocytes in the diaphyscal marrow near the lin of union

Macroscopical description. The pnearance in general corresponds i that found in the previously described experiment. The ormal bon has increased of cm. while to operated bose has only increased of cm. The epiphysis, however is denser. The epiphysical cartiage line has not the same tendency it separate and the disphysical part of the transplant is less dense than normal.

Experiment 7 Duration 23 days. Dog 3 13L,

Summary on Autotransplantation of the Epi physical Cartilage Line

This series of aut transplantations of the epiphyseal cartilage line is not sufficiently complete to definitely determine each step of the degenerative and regenerative processes. However, there are enough section to allow for the following deductions.

An early re-toration of the marrow takes place in the tran plant a 1 hown in the

Section at the twenty thirl day

The trabecula of the transplant at first de generate and then regenerate by the formation of osseou the ue beginning at the periphery

The epiphy scal cartilage line shows an early degeneration and at 3 day there is a definite line of cleavage separating it into a distal one third and a proximal two-thirds. The degineration progres (sels) increases with the length of the experiment and it 135 days only a slight remnant of the line is found.

Changes take place in the marrow of the hot imilar to thee at the line of union in the transplant

OMPARI ON OF REIMPLANTATION AND AUT TRAN PLANTATION OF THE EPIPHA EAL (APTILAGE LINE

In both aut tran plintation and reinglan titling change in the tranglant take place in mediately after exiling. The marry begines near the all seen in the cition to a factor that the near the number of the cition to the number of the cition to the number of the cition that the number of the numb

The change in the epiphyseal cartilage line are variable unles the experiments are performed in exactly the ame way. More of less injury at the time of operation or the ize if the transplanted segment seems to in fluence the realt. Thu in a reimplyinta in experiment at 1, day there is a more active degeneration than at 3 day but it is found that the articular cartilage 1 displaced in the 1, day experiment thereby affecting the result. The processes of degeneration are very imiliar in the reimplantation and autotransplantation but are perhap a little more rapid in the latter.

REIMPLANTATION OF VAPYING LENGTHS OF THE EPIPHYSEAL END OF THE METY CARPAL AND THE METATARSAL BONES

Method Atter exposing the metacarpal or metatarsal the bone is sectioned at the desired place. The capsule of the joint is opened and the entire tran plant including the articular urtace is removed care being excressed not to injure the epiphysical cartilage line. The bone is immediately re-implanted. It is held in place by a uture passed through the cortex of the host and transplant and by sutures paising from the surrounding tissues over the articular end of the bone. Different lengths of bone are used

in the various experiments in order to de termine if the size of the transplant exerts any influence on the results.

Experiment 1 Duration 1 days. Two-thirds length, Dog 30-38 growing animal

Macroscopect description Good healing is present b tunken is not firm. There is no increase in kenth of either operated or normal bone. The articular cartilage appears in mail. The marrow of the trimapiant is pule than in mail. The cp physical cartilage line is broadened and there is a pule while line extending through distal neither of the pule while line extending through distal neither of the cartering through through the cartering through the car

Microscopical description. The articular carti lage appears normal. In this section the normal relation of the articular cartilage to the eniphyseal cartilage line, as is found in the carry developmental stages, is easily made out. It is continuous with the epiphyseal ossifying cartilagmous layer of the epiphyseal line (Fig 7) The marrow of the sol physis is almost entirely ecrotic (Fig 8) The nucles of the trabeculæ appear pal and are evidently degenerating. The epiphyseal cartilage line is awollen (F)s 7) In the distal one-third the cartilage columns are distorted and there is more inter cellular hyaline tissu than usual. The remainder of the epiphyscal line appears normal. In the metaphysis the provisional ossification zone is of normal arrangement but the nuclei of the cells are indistinct. The marrow of the disphyses! part of the transplant is necrotic. The nuclei of the tra beculæ take a pale stain and show evidence of early degeneration. The cortical bone is made p of nale staining nuclei except beneath the personaum where there is some new osseous tissue. The bon of the host appears normal

Experiment Duration 3 days On third

length. Dog 30-38 young animal

M croscopical description The ppearance is

The hone of the bost poears normal

similar to that described in the previous' speciment. Microscopical description. The structure cartilege ppears ormal. The marrow of the epichysis is necrotic. The urter of the trabecule of the epichysis are pale but do not appear to be so extensively degener ted as in the previous experiment. The epichysisal cartilage line is broader than cornal but it cellula elements appear almost cosmiting cartilage are in part degenerated those pear the pertiplecy show evidence of poolitics.

In comparing the last two experiments it is evident that the degenerative processes are more rapid and extensive in the transplanted segment which is the kingest

Experient 3 Duration days On half

Macroscopical description Good healing is
present but owing t the displacement of the
transplant it is ununited (Fig.) There is pra

tically o growth of the operated and the non-

operated bon

Microscopical description The articular carti lace appears a small except to a librous thickening on the outer surface and small areas in which the nucles stain poorly The marrow of the epiphysis is substit ted by ascula tibrous, and fatty tissue with here and there some necrotic marrow. The trabecula of the epophysis stam rather homogeneously the clei appearing as shadows. There is evidence of early regenerate o th periphery of the trabeculæ These cells look like young outcoblasts and ppear to be closely related to the surrounding throus tues. The epiphyseal carti lag line is degenerating as a shown by the frag mentation of the cartilag ells and distortion in the regula olumnar arrangement. There is definite line if clear ge in the proximal one third of the enaphyses! cartilage line (Fig. 1) the metaphysis there is very little evidence of omitication of the cartilage, except tome border where there is a rich etwork of osteoid tiesus The intervening marrow is abrous as is the marrow f the diaphysis. The trabecular i the diaphysis a scanty showing homogeneous entral part about which there are osteoblasts forming new bone The cort of the transplant is made up of tw. parts, an inner homogeneous degenerated part and an outer cellular part composed I young ow f rmed osteoul tusu. In this experiment the corte of the host and the transplant are in poor c ntact and t is interesting t ote that the great est amount of ew osseous tissue is produced from the personteum and endosteum on the side most distant from the host (Fig. and) It is evident that this regener led turbue is formed by the personteum of endosteum of the transplant independently of the bort. The ort wolf the host is normal (Fig 3) Exper me 1 4 Duration 1 days Two-thirds

Micro-copical d simplion. The articular card later appears ormal epi for a slight fragment-tion of some of the elb f the maddle layer and the pale staining of the inner layer. The marrow spaces of the epiphys are occupied by a loose mesh ork of somecul mass in which are uncrous ellular element ungestung the beginning

format! of the marr w Th bone trabecular appear degenerated but som ar begrunng to about regeneration as is evidenced by a prollieration of outcoblasts on the periphery to form young bone.

There is also a considerable formation of ub periosteal bone on the lateral border of the enphysis. The epiphyseal cartilage line 1 wider than normal. At one border there i a large defect in the cartilage but aside from some fragmentation and irregularity in the distal one third of the cartilage columns the epiphysial cartilige line i of normal appearance. On the epirhyscal side near the epi physical ossitving cartilag la r which tains poorly there is considerable amount of newly formed osteoid tissue. In the metaphy is there is a lack of the active ossincation of the cartilage columns which appear elongated and are separated by hbrous tissue instead of marrow. The marrow spaces of the diaphysis are filled with loose fibrous tissue in which there are a con iderable number of marrow The trabeculæ of the diaphysis are very numerous and the older ones show definite evidence of regeneration about their borders. The cortex of the happy is of the transplant is made up of old degenerated bone about which there is newly tormed osseous tissue which seems to arise from the Deri ostcum indosteum and in the haversian canals The most marked regeneration is on the plantar side which is in part due to the ingrowth from the There is definite vidence that the bone of the transplant has some property of forming new bone independent of ingrowth from adjoining bone of the host. The elements of the host appear normal

E p riment i Diration 38 days Three fourth length Holes bored in the transplant

Dog 3 -40k age 2 months

Via roscopical description. There is good healing and union 1 frim. There is no growth of the operated bone while the normal bone has in reased of tim. The roemignogram show the shortening and absorption of the transplant (Fig. 14). The articular cartiling appears normal although it is much thicker than normal. The epiphyseal end of the transplant is darker than the disphyseal part the latter being quite pale when compared with the normal. The piphysical cartilage line is quit distinct but is tunner and more irregular than normal. Provincial to the epiphyseal cartilage line in the metaphyseal region is a white band extending across the bone.

Microscopical description The atticular cartilage is much wider than normal and there is a tendency for the ell to form in groups. There is an occasion I cell shadow but little evidence of deg ners on every us is hown by the poor stain ing of some of the ells of the inner layer. The marrow of the epiphysis is pravia ally all fibrous with a f w scatter d marrow-el ments in some parts. The trabecular of the epiphysis a c almost entirely regenerated some how ver still show the dead centers with new oss-cost situate about the perity frequency large helps both in the columns and at the junction with the metaphysis. The epith year ossiving cartilage layer is well main

The metaphy: is r pla ed by nbrou tissue and osseous trabeculæ. The marro of the diaphysis is fibrous but bec mis quite. Ilular at the end near the hot a though the latt river playing a considerable role in its rain rat n Numerou o teoblast are present. The traherulæ show advanced regeneration, those farthest away from the host are in the molt advan ed tage again indicating the independ new or the regen ration of the differ nt element of the tran plant. The cortex of the transplant t thin and in places it is separated by bands of fibrou tissue. The appear ance is lue to the iner with of fibrous tis ue into the holes that are bor I into the transplant degenerated parts ar being substituted by new periosteal and endosteal bone which does not appear to be definitely related to the host line of union ther is still considerable abrous tissue and very little tenden v of the Ortical bone of the host to invade the transplant. The host is of nor mal appearance exect at the line of union where there is some fibrous tissue invasi n of it marrow cavity

Experiment 16 Duration 44 days One hallength. Dog 33-44R ag 1 months

Macrosopical description There is good healing and firm union. There is no growth of the operated bone while the normal bone is o m. Inger than it was at time of operation [Fig. 15]. The articular cartilage appears white in comparison to the pink color of the other bones. The capsule of the joint appears normal. On langitudinal section the transplanted piece is pale the articular cartilage is broader than usual, the epiphyseal line is indistinct and there is a white band across the metaphysis.

Microscopical description. The articular cartilace is broad and is divided into two different regions an outer in which the nuclei are stained deep and an inner in which they are stained light. The cells themselves do not appear to be degenerated The marrow-spaces of the epiphysis are occupied by loose t brous tusue in which are scattered nu merous new formed matrow-elements especially on the durial surface. The trabeculæ of the epiphysis are partially regenerated. There are also some new tormed trabeculæ. The epiphyseal cartilage line is in an advan ed stage of degeneration (Fig. 16) The epiphyseal ossifying cartilage layer is best maintained but even that is being invaded by osseous and fibrous tissue. The columns of cartilage of the epiphyscal line have been entirely replaced by fibrous and osseous tissue. At the periphers of the epiphy seal cartilage line there is a considerable proliteration of cartilage beneath the perichondrium both in the region of the columns and in the osify ing cartilage of the epiphy is (Fig. 16) ossifying cartilage columns of the metaphysis are entirely osseous and between them is abrous tissue The marrow of the diaphysis is partly regenerated being intermingled with vascular connective tissue The trabeculæ of the diaphysis are fully restored in fact there is a marked increase of osseous tissue throughout this part of the transplant. The cortical bone is quite irregular and appears to be under going absorption about its borders. The line of union is bony and it is possible that the transplant is being regenerated by the host. The host appear normal

Experiment Durati n 5 days One-third length. Dog 34 43L, ago 14 months

Macroscopical description There is good heal ing and firm union. The growth of the operated bone is o.q. c.m. while that of the non-operated bone is t. cm. (Fig. 7) The joint capsule is thickened. The articular extillage is blue and has lost its normal form. On the longitudinal section the marrow ppears yellowish the epophysical cartillage line is absent and the cortex is thunner than normal.

Microscopical description. The articular art lage is of normal arrangement and the cells appear quite intact. The marrow of the epiphysis is normal being composed of marrow-element.

fat. Some of the turbecule are normal whill them are made up f a cartilaginous center or rounded by normal bone. In some of the earliest ratges the trabecule are practically all osseous and it is rather difficult to explain the persist nor of the cartilage line is represented by a thin osseous cartilage line is represented by a thin osseous cartilaginous band extending across the bone (Fig. 8). The m taphyseal explosion is occupied by f try mar row. The marrow cavity of the disphysia falled with normal fatty marrow in which are feasurement of the control of the control of the transplant is of n rmal prearms except that it not arranged in the normal, even and regular manner. There is a considerable amount of crossion on the outer surface and osteoclasts are quite numerous. The hare of nion persists as this hand of bone. The bone of the host appears

normal.

The operated bone shows 0.45 cm. Increase in length since the tim of operation. This is the only instance in the series in which there is any appreciable growth. It is possible that under some credibility of the series in which there is any appreciable growth. It is possible that under some credibility of the series of the series of the credibility of the property of increasing the length of the bone. In spate of this fact, the normal bone has increased three times as in the as the operated bone and its epiphyseal line per sitt, while the epiphyseal line of the transpit red bone has disappeared (Fig. 7). Therefore, even if the transpit in the property of the production of the pr

Macroscopical description. There is good beating and firm union. The gro th of the operated bone is 0.15 cm. while that of the normal bon is 45 cm. (Fig. 19). The entire specimen was preserved in Kalseriller.

Summary on Reimplantation of Varying Lengths of the Epiphyseal End of the Metacarpal and Metatarsal Bones

The arti-ular cartilage shows only alight changes in the inner layers which is indicated by an irregulanty in the arrangement of the cells and the loss of some of the nuclear tain.

The marrow undergoes an early necrosis. It is possible that some of the cells may persist and later share in the regeneration but this point annot be lemnially determined. The later stages show the marrow spaces tilled with throus connect it itsue after which there is a gradual restoration of the matrix.

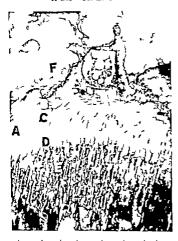

The trabecular even at 12 days show disappearan e of their nuclei, and in the later tages there is a gradual regeneration which takes place through a peripheral substitution of the old-bone. This regeneration occurs independently of the h-st and seems to bear some relation to the surrounding fibrous tissue.

The epiphyseal cartilage line at first shows a crumbling of the cells at the junction of the proumal two-thirds and distal one third. Then a issure appears in this region following which there is a ontinuous and progressive degenerate in of the entire cartilage. The mre peristient part is the epiphyseal cartilage band. There is only a very limited attempt at regeneration in the parts just beneath the perichondrium.

The marrow of the diaphysis undergoes the same changes as it does in the cplphysis and there is no earlier regeneration in spite of its close proximity to the host, although it might receive additional elements from the host.

The changes in the trabeculæ of the diaphy sis do not differ from those in the epiphysis.

The cortical bone at first degenerates and is then regenerated by new bone which is formed from the endosteum and periosteum in some of the sections there is a considerable amount of crosion beneath the perfosteum It is difficult to determine whether the bone is later substituted from the host, but at first it is definitely formed from the original periosteum and endosteum of the transplant.

almost a normal structure. The regeneration seems to take place independently of the host. The exact method and source of the regenerated marrow could not be determined.

The trabeculæ of the epiphysis at first undergo degeneration, and then by a process of new formation beginning at the periphery are completely regenerated

The epiphyseal cartilage line undergoes a progressive and complete degeneration. There is some regeneration beneath the pen chondrium in the early stages. This new cartilage does not possess the normal property of increasing the length f the bone.

The marrow and trabeculæ of the disphysis are subjected to the same changes as are the marrow and trabeculæ of the emphysis

The cortex at first h ws extensive degeneration but later there is regeneration from the periodition and endosteum independently of the host. However in the later stages there is considerable bone erosion on the surfa e and in rous those precisions.

COMPARISON OF REIMPLANTATION AND AUTO-TRAN PLANTATION OF ARRIVE LEMOTHS OF THE FERMINISEAL END OF THE META (ARPAL AND THE METATARSAL BOYES

The changes in the articular cartilage are more marked in autotransplantation than in reimplantation although even in autotransplantation they are not very extenave

In both autotransplantation and remplan tation the marrow of the epiphysus very early becomes necrotic. The necrotic marrow is replaced by fibrous tissue which in turn is substituted by new marrow-elements. The regeneration appears to take place more rapnully in autotransplantation.

The trabecule of the epiphysis undergo practically the same changes in both autotransplantation and reimplantation there being at first degeneration and later gradual new formation which begins on the periphery of the trabeculæ. The rate and degree of degeneration and regeneration are relatively the same in each case.

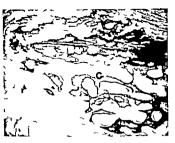

The epiphyseal curtilage line undergoes a gradual and persistent degeneration in both autotransplantation and reimplantation. In some cases the regeneration seems to be more rapid in the reimplantation than in autotransplantation while in others the opposite seems to occur. In general the processes are smillar in both instances.

The marrow of the dusphysis undergoes the same changes a in the cipulpass in board autotransplantation and reimplantation. The changes take place in about the same order and degree in both cases alth ugh there is perhaps an earlier regeneration in autotransplantation.

The changes in the trabecular f the diaph vsis are similar to those which take place in the enhances.

The cortical bone in both autotransplantation and reimplantation at first degenerates and is then restored by means of proliferation from the penosteum endosteum and about the haveranan canals of the tran plant. There is crosson about the surface of the cortex in both groups but it is more intense in the auto-transplantation. Although there is independent regeneration of the cortex from the periosteum and endosteum of the transplant, it can not be denied that the host plays a part in the new formation especially as concernathe permanent bone.

Firm union of the transplant and host occurred in both types of experiment.

Summary on the Two-Stage Autotrans plantation of Varying Lengths of the Epiphyseal End of the Metacarpal and the Metatarsal Bones

The articular cartilage is well maintained in every case except in Experiment 36 where there is some evidence of degeneration of the inner layer

The marrow of the epiphysis does not unbut immediately after the second operation but immediately after the second operation degeneration occurs. It at first becomes necrouse then fibr us, and finally it regenerated. The regeneration is similar to that which occurred in reimplantation and autotrans lantation, although it takes place more rapidly.

The trabeculæ remain unchanged during the first tage but immediately foll wing the second operation they undergo degeneration. Regeneration then takes place in the usual manner by peripheral formation and substriction with new osconus tissue.

The emphysical cartilage line is well maintained during the first stage and though it functionates that property is restricted to a considerable degree. Meet the second op-

paler than normal

Summary on Reimplantation of an Entire

Metacarpal or Metatarsal Bone

The articular cartilage undergoes slow de generation and in some of the experiments a substitution by tibrous tissue occurs.

The marrow undergoes an early degeneration and then regeneration takes place. This regenerated marrow persisted as long as any of the other osseous parts.

The trabeculæ degenerate early Later by means of regeneration beginning at the penphers they are completely re-formed. In the more advanced stages they again show degenerative changes.

The epiphyseal cartilage line undergoes progressive and complete degeneration. There is some cartilage regeneration beneath the perichondrium at the edges but this does not persist

The marrow and trabeculæ of the diaphysis undergo the same changes as they do in the

epiphysis

The cortex at first decenerates and then is regenerated by new bone formed from the periosteum endosteum and about the haver sian canals As the observation did not ex tend beyond 208 days it is hard to say den nitely the fate of this bone but from the various pictures presented it seems as though this newly formed bone again degenerates and finally entirely disappears or only a small remnant remains

There is always complete failure of growth after reimplantation of an entire bone

AUTOTRANSPLANTATION OF AN ENTIRE MUTA CARPAL OR METATARSAL BONE

Method The entire metacarpal or meta tarsal bone is raised from its bed and inter changed with a corresponding bone of the opposite foot

Experiment 51 Duration 36 days Dog 1 L

split at distal en lage o months.

Macroscopi al description There is no growth of the operat d bone while the normal increase is The point-capsule is thickened and the cavity contains turbed fluid. The articular car tilage is rough. The distal end of the bone appears enlarged The epiphy sis is composed of a gelatinous cartilage looking material. The marrow-cavity contains soft degenerating marrow. The cortex is

irregular and thickened Microscopi al description. The joint cartilage shows a different degree of staining in the outer and inner parts in the latter the nuclei stain poorly There is a fibrous tissue substitution of the marrow of the epiphysis which contains collections of poly morphonu lear leucocytes. The trabeculæ of the epiph) are omposed of a homogeneously stained center without nuclear stain about which is newly formed out old tissue. The epiphyseal cartilage line is almost entirely absent and a fissure extends through the region. The metaphysial cartilage columns are scanty and appear to be degenerating The marr w of the diaphysis is throus and the trabeculæ show mark d evilen e of degeneration The ortex is composed of a homogeneous nonnu lear ontaining tissue about which there is some n wly formed bon but there is more evidence of absorption

Exp m m 52 Duration 36 lays Dog 17R split entire age o () months

Macroscopical description The bone is o 5 cm shorter than at time of operation while the normal bone is 0.4 cm. longer Joint cartilage is rough, dis tal en l of bone necrotic and epiphysis absent

Microscopical description. On cross section th marrow cavity is seen to be filled with fibrous tissu The nuclei of the cortex stain poorly and the ar h ltecture is not so regular a normal. One one 11 there is a considerable am unt of periotcal n formed cartilage an Losteoi Lus u

Experiment 3 Duration So days Dog

5L age 3 5 months

Macroscopical description. The healing is good The operated bone is o 6 cm horter than at the time of operation while the non operated bone 1 o 1 m longer The marrow appear n rmil The epi physeal cartilage line is n't di t ngui hable

Microscopi al description. The artifular cartilace on one side acrears tairly normal while on the other side it is practically r pla id by pbrous tissu The marrow and trabeculæ of the epit his are not The epiphysial cartilage ling is almost on tirely absent only a mall band of ossitving ar tilage is present. This band appears nearer to the articular cartilage than a rmil as if there is a collapsing of the epithy i. The marro v of the diaphysis is normal. The trabecule are normal although some contain what appears to be d ad bone in their centers. The uter urta e of the cortex is very irremilar and eroded alth ugh the general structure of the bone is normal

Experiment 54 Duration 80 day Dog to-

sR age a a months in used

Macroscopical description. In this experiment holes are bored into the bonc at various places There is 0.5 cm shortening of the operated bone On section there is a large artilliginous mass in the region of the epinhyseal artilage line. The proximal end of the bone is smaller than normal

Microscopical description. There is a mass of fibrous tissue extending into the joint chondrum is thickened and in some places the cartilage is pierced by fibrous tissue tilage that remains shows a peculiar arrangement of the nuclei and it is difficult to determine whether it is degenerating or regenerating. The marrow and trabeculæ of the epiphysis and diaphysis appear normal. The epiphyseal cartilage line is represented by a thin hand of ossifying cartilage at one end of which is a large amount of perichondrial fibrocartilaginous tissue, which is undergoing ossification. The cortical bone is of normal structure although there is extensive erosion on its surface

When this experiment in which holes ire bored into the transplant is compared with the previous one which was left intact it i noticed that the various parts of the latter are best maintained

Experiment 55 Duration of days Dog 8 3L age 6 months

Macroscopical description. The transplanted bone is o 3 m shorter than it was at the time of the operation. There is only o cm growth in the normal bone. There is some thick ning of the

joint-capsul and irregularity of th articular sur face. On section the marrow-cavity is found to be occupied by cancellous bone in which are scat tered marrow elements. The cortex is thickened. bregular and quit dense thus giving the bone a larger and more irregular appearance than normal

Microscopical description. A cross section at the dutal end shows an abnormally shaped marrow cavity containing fairly normal marrow The trahecule are more numerous than normal and in the centers f some there is degenerated bone cortex, the nuclei of which are well stained, sh was a distortion of the haversum systems and about the outer surface, which is rough, are many osteoclasts The periosteum has lost to normal pressure so that the surrounding fibrous tissue penetrates into the c rtex. The proximal end is similar with the exception that the marrow is not so cellula

Experiment 56 Duration og days Dog

5 mo the foreloot

Macroscopical description. Only a small remnant about cm long of the distal part of the transplanted bone remains. There is no growth of the normal bones.

Microscopical description. There is dense fibrous tues surrounding the paece of bone. The bone contains mature marrow and trabeculæ of normal appearance. The cortex is irregular and fibrous these penetrates the bone substance in some places. There are numerous esteoclast scattered about the periphery There is a distinct periosteum present.

Experiment 57 Duration on days. Dog 1 1L. age o months, hind foot

Macroscopical description. There is no increase in length of the transplanted or the normal bones. The articular surface is rough and at its distal end the bone is fused with the adjoining bones

Microscopical description. On cross section of the dutal end there is normal piece of bone adherent to the transplant. On comparing the two. the transplant is m ch more irregular in outline and in transpenent of the haversian systems. The perlosteum has lost its distinguishing structure and the fibrous tissue is in intimate ontact with th bone. Many osteoclasts are present. The marow and trabeculæ are of normal atructure but likewise irregularly arranged.

Experiment 58 Duration a55 days Dog

old dog

M croscopical description. The art cular car til ac appears almost pormal. On longstudinal section the marrow-cavity is irregular and the mar row ppears paler than usual. The general appearance is one of al w degeneration.

Microscopical description. The articular ca tilage is egular in outline but the clei tal. stam The marrow toward the epsphysis is of the mature f tty variety, while m the diaphyseal part it is replaced by abrous tissue. The trabeculae for the most part contain poor staining nuclei. In

the cortex the nuclei take a poor stain, excepting those immediately beneath the periosteum, where there appears to be newly formed osseous tissue.

Summary of Autotransplantation of an Entire Metacarbal or Metatarsal Rone

As far as can be ascertained from this in complete series there appears to be more de generation in the case of young animals than in the older animals.

In the young animals the articular cartilage shows marked degeneration and substitution by fibrous tissue. In the old animals the articular cartilage is well preserved even at 255 days.

The marrow at first degenerates and then becomes fibrous. Later it regenerates and persists for a considerable length of time.

The trabeculæ degenerate at first as is seen in the 16-day experiment and then regenerate by a process of peripheral new for mation.

The epuphyseal cartilage line undergoes a progressive degeneration. There is some new cartilage formed during the early stages be neath the perichondrium at either border but this eventually disappears

The cortex at first loses its nuclear staining then regenerates and finally undergoes a slow absorption The periosteum seems to disappear and the fibrous tessue and osteoclasts gradually absorb and replace the bone

COMPARISON OF REIMPLANTATION AND AUTO-TRANSPLANTATION OF AN ENTIRE META CARPAL OR METATARSAL BONE

The articular cartilage shows more rapid and extensive degeneration in young animals after autotransplantation of an entire bone than after reimplantation. In older animals the difference is not so evident nor is the process so rapid.

The marrow in both cases degenerates at first and then becomes fibrous and finally regenerates. The processes are about the same in reimplantation and in autotransplan tation.

The degenerative processes of the eniphyscal cartilage line are the same in both reimplantation and autotransplantation gradual complete progressive degeneration with only a slight temporary regeneration at the periphery beneath the perichondrium

The cortex is similarly affected in both reimplantation and autotransplantation. At
hist there is degeneration and then regeneration after which the periosteum loses its
tructure and a slow absorption occurs
throughout the entire bone. Though sufficient time has not elapsed in these cases the
indications are that there would be complete
disappearance of the transplants if a longer
period were allowed to elapse before terminat
ing, the experiment. The transplants from
older animals were able to withstand the
degenerative processes better than those from
younger jumials.

There is complete failure of growth in both reimplantation and autotransplantation of an entire metacarpal or metatarsal bone.

The splitting or incising the bone did not haver the transplantation on the contrary it hastened the degeneration

DISCUSSION AND REVIEW OF THE LITERATURE

Helferich (2) in some experiments per formed in rabbits in 1899 in which he reim planted the lower epiphyseal cartilage line of the ulia came to the conclusion that the epiphyseal cartilage line under favorable conditions retained its property of producing length growth although he noted there might be a lessening of that function Enderlin (3) who made the microscopical studies of these preparations decided that the epiphys cal cartilage his retained its vitality to a large extent. The parts near the periphers were best maintained while those at the center showed evidence of degeneration.

Z ppi (4) found in autotransplantation f the epiphysis a regular healing in and formation of new bone but in heteroplastic tron plantation there was a complete failure

Galcarzi (5) found in both autotransplan tition and homotrin plantations calcifica tion of the cpiphs i and complete loss of function

Rehn and Wakabaya hi (b) from a series I experiment on two-months old rabbits in which they periormed homoplastic transplantation of the head of the radius concluded that the epiphy-cal cartilage fully maintained

its histological structure and function after such transplantati n Their experiments are open to criticism because they do not rule out the greater growth that takes place from the distal epiphy 1 of the radiu. In their microscopical descriptions they mention cer tain degenerative change accurring in the epiphyseal curtilage line at 28 51 3 and 42 days after operation which is but ruthe nor mal time for o incition of the epiphy cal line in rabbits (fourth to fifth month) the present arti le the results in autotran plantation are les taxorable than in reimplantation. It is more than likely that the degenerative changes would be more marked in homoplastic transplantation and that the result would be juste contra dictory to those of Rehn and Walabaya hi Obata who performed a series of experi ments exactly imilar to the scot Rehn and Wakabaysahi dies nit agree with their functional nor their microscopical findings

During the same year 1912 Axhausen (7) article appeared in which he reported the results of his experiment on young rat and rabbits. He tran planted the lower fourth of the femur from a growing rat to the subcuta neous tissue of another rat. He found some degeneration of the inner layer of the artic ular cartilage at the sixth to twentieth day after which there wa regeneration. The marrow of the epiphysis and diaphysis at first degenerated, then became fibrous and at a very late period was regenerated in the ephiphysis -The trabeculæ at first de generated and then regenerated. The epi physeal cartilage line showed in the early stages a shrinking of cells and at 20 days only the peripheral parts remained alive later stages aside from a slight proliferation near the periphers the entire line was substituted by fibrous tissue. The cortex showed an extensive degeneration up to 30 days but in the older stages there was considerable regeneration. In a similar set of experi ments on rabbits the results corresponded quite well to those found in the rats. In another group of experiments thin sheets of articular and epiphy cal cartilage of the femur of rabbits were tran planted under the skin on the back of another animal. The marrow

was substituted by fibrous tissue except be neath the articular cartilage and near the surface. The bone trabeculæ appeared to undergo degeneration with very little evi dence of reveneration. The articular car tilage showed in the later stages a substitu tion of the dead inner layer by a proliferation from the perichondrial layer. He also transplanted the patella, either intact or split in two pieces from one rabbit to the subcuta neous tissue of another rabbit. The bone showed shrinking of nuclei at 24 days empty cells at 45 50 and 70 days. There was an early necrosis of the marrow and complete degeneration at 24 days. At so days there was beginning organization which was completed at 70 days. The inner layer of the articular cartilage showed a beginning shrink ing of the cells at 10 days which was more marked at 18 days. At 50 days there was some proliferation of the cells and at 70 days there was evidence of resorption of the car tilage. In the cases where the natella was cut into two pieces the cartilage showed some necrosis on the surface due to the trauma

While the present work was being completed the following articles appeared and they will be reviewed in the order of their publication

Von Tappener (8) performed three re implantations and eight homotransplantation experiments on dogs, at the ages of one and one half and four and one half months. In the reimplantations he found no changes in the articular cartilage. The marrow of the enaphysis and disphysis showed fibrous changes at first, after which regeneration occurred. The trabecular at first decenerated and were then reformed. There were practically no changes in the epiphyseal cartilage line even after six months. The cortex at first degenerated and then was regenerated There was no disturbance in the normal growth These findings in reimplantations are entirely at variance with those of the present article both as regards the normal microscopical appearance of the epiphyseal cartilage line and the normal longitudinal growth of the bones which he reports. As his experiments were performed under exactly the same conditions it is difficult to explain or offer any reason for such wide variation in the results. His micro-copical descriptions on homoplastic transplantations correspond closely to the autoplastic experiments described in the pre-ent paper. He ascribes some power of the epiphyscal cartilage line to increase in length even after homotransplantation again disagreeing with the findings of the author.

Ohota (o) has made a very omplete study of the transplantation of the epiphysis in his work on joint trans lantati n He performed reimplantations autotrunsplantations and homotransplantation of the metatarsophalangeal soint either with a part for the entire metacarpal and phalanx. He found a disturbance in growth in every in tance the greatest being in the case of homoplastic transplantations. The transplanted joint cartilage maintained its normal form but appeared cream white and in later stages erosions appeared on its surface. The union of transplant with the bost was normal in every case except in homoplastic transplanta tions where there was a pseudo-arthrons general the above macroscopic findings agree with those of the present investigation except that Obata did not find such a marked failure of length growth in his reimplantations Obata a microscopical findings on reimplanta tion, he describes degenerative changes in the articular cartilage as early as o days which were more marked at 35 days then regenera tive changes at 50 days and again degenera tion in the middle part at 70 and 100 days. At 104 days he says it is in normal condition It is difficult to analyze these changes and he offers no explanation for the variations in the processes. He also described a progressive degeneration of the epiphyseal cartilage line until the tiftieth day after which there oc curred a partial degeneration followed by a regeneration. He ascribed almost normal functional properties to this regenerated epiphyscal cartilage line. At 70 days he described an extensive degeneration of the epiphyscal cartilage line. It is difficult to explain the discrepancies in his findings in that there was an extensive degeneration at 35 and 70 days while at 50 days the cartilage was so well maintained. It is possible that

under some especially favorable circumstance the transplanted epiphyseal cartilage line did not undergo the usual rapid degeneration as in the other cases In comparing Obata s findings on reimplantation with those of the present work there is a considerable uni formity except that he describes extensive degeneration of the articular cartilage while in these experiments the articular cartilage proved to be the most resistant of any of the transplanted tissues. This difference might be due to the fact that he transplanted the entire joint with the intact capsule which perhaps prevented the early inflow of nourish ing fluids as is possible in the case where only one half of the joint is utilized. Neither is there an agreement as to his statement that the couphy-scal cartilage line can regenerated so a to continue the length growth of the transplanted bone. In the autotransplanta tion he likewise describes much more extenive changes in the articular cartilage than is tound in the present work. Otherwise the changes correspond fairly well to the changes that are described in this series of experi In Obata's homoplastic experiments he found changes to be more extensive in the cartilage than in reimplantation or autotransplantation with very little evidence of regeneration There was also less tendency to regeneration of the marrow trabeculae and cortex. In case of non related animals the degenerative processes were more rapid ind extensive. In the homoplastic transplantation of the head of the radius he found the same degenerative changes throughout the tran plant as in the other cases epiphyseal cartilage line underwent a progressive degeneration with practically no regeneration. Thus he does not agree with Kehn and Wakabayashi who performed imilar experiments and described complete retents in of structure and function of the cpiphyseal cartilage line Heller (10) performed reimplantations and

of the ulaa of rabbits and goat He found the least amount of shortening in reimplantation while the greatest amount was in homoplastic tran plantation in non-related animal. He concluded that a practical use

of the epiphyseal cartilage line with a more or less large piece of bone attached could not be utilized in reimplantation and certainly not in homotransplantation. He said that in reimplantations there was some regeneration of the epiphysial cartilage line and a not in considerable amount of bonc apposition but nevertheless the bone growth was retarded In homoplastic transplantation he found some perichondrial regeneration but that there was no tendency for a physiological utilization of this in the epiphysial cartilage line larger the animal the less favorable were the results and the more rapid and exten ive the resorption even to complete disappear ance of the transplant. He predicted that it might be possible by u ing very thin pieces of the combineral cartilage line to obtain some successful result, and in a hort note it the end of his article intimated that he had obtained favorible realts by the use of thin sheets in autotransplantation. The finding of Heller agree tairly well with those described in this paper except that he report more or less growth after reimplantition of the distal end of the radius and ulna on account of the bending of the extremity does not offer so favorable an experimental method as does the use of the metacarpal or the meta tarsal bones

Minoura (11) transplanted the metatarsophalangeal joints either intact or split longitudinally of two months-old rabbits into the back subcutaneous tissue liver or abdominal cavity of the same or different animals In some cases the joint was placed in Ringer's solution before transplantation or was removed from a dead animal. These experiments do not correspond to those of the present work because the transplant was placed under unnatural conditions but on account of a certain agreement of the early histological changes they will be reviewed He found that the transplanted joint became encapsulated by the tissue of the host and that the healing was always the same whether it was in the muscle subcutaneous tis ue or abdominal cavity—In the longitudinally split bone the organization took place more quickly thin in the entire bone and there wa little difference in the processe if the joint was allowed to remain in Ringer's solution before transolantation. The joint cartilage re mained intact for a considerable time and always showed a cartilage-cell regeneration on the periphery. The marrow decemerated and was substituted by fibrous tissue and later by fat. The trabeculæ of the epiphysis degenerated and later were substituted by new formed bone which however was not permanent. The epiphysenl cartilage line underwent necross and absorption only the parts of the problemating zone near the periph ery showed multiplication of the cartilage cells. The periosteum always showed new bone formation in the inner layers but the new formed tissue finally underwent absorption. In these experiments there was no possibility of the bone of the host playing a part in any of the regenerative processes The findings agree very well with those of the present work except that in Minoura's experiment there was not the extensive regeneration and there was a lack of permanency of the new formed tissue. Thus it shows that there are certain regenerative processes that can take place in a transplant without the aid of the host, but in order to have lasting qual ities some additional elements from the host are necessary. The changes in homonlastic transplantation were similar to those of autofransplantation although they were not so marked nor so permanent. In none of the experiments was there any increase in the length of the bone after transplantation

(ill (12) reports eleven experiments per formed on full grown animals in which he made autotransplantations of the entire metatorsal bones. Infection occurred in most of his experiments but in spite of that fact, he says five of the transplanted bones were practically normal at the end of eight months. He found no evidence of dead bone on microscopic examination in this expen ments in which there was only slight infec-In comparing Gill's results with those of similar experiments in the present paper there is a consideral le variation in the find In pra tically every case in the present experiments there was macroscopic and microscopic evidence of decentrative changes after the transplantation of an entire

bone The changes took place earlier and were more extensive in the young animals

SUMMARY

The epiphyseal cartilage line ceases to functionate after reimplantation and autotransplantation either when transplanted by itself or with a small or a large piece of adjoining diaphyseal or epiphyseal bone or even when transplanted as an entire intact bone. The longitudinal growth ceases in every case The first change after transplan tation consists of a fragmentation of the car tilage columns near the epiphyseal ossifying Later there is a disappearance of these cells Then there is tibrous substi tution of the remaining parts, and finally ossification occurs as in the adult animal. The only evidence of regeneration is near the periphery beneath the perichondrum which part seems to return its property of producing cartilage. This new cartilage possesses none of the length-produmer fun tions of the normal emphy-cal cartilage line. The coiphysical cartilage line is the least transplant able of any of the components of bone.

2 The arti ular cartilage undergoes practically no changes after remplantation. In autotransplantation there occurs at times evidence of degenerative and regenerative changes. In some of the experiments of longer duration there is a partial substitution by fibrous tissue. The arti-ular cartilage. Here the greatest possibilities of successful.

tran plantation of the various parts of a bone 3 The marrow of the transplant appears to undergo an early complete necrosis. It is possible that some of the cells persist because of better conditions for nourishment, or have a greater resistance and are later the source for the regeneration of the marrow the necrous of the marrow the spaces are filled with fibrous connective tissue. At a still later period scattered marrow-cells are found in the fibrous tissue and there is then a gradual reformation of the marrow The exact method of regeneration cannot be definitely determined. Whether it bears any relation to the newly formed capillaries or arises from the persisting marrow-cells of the transplant, is difficult to ascertain

- 1 The trabeculæ show early evidence of degeneration as is indicated by the loss of taining property of the nuclei. The first indication of regeneration is seen on the periphers where a layer of osteoblasts are found. The later stages show a proliteration of these cells to form osteoid tissue which gradually replaces the old bone to form the new trabeculæ It is impossible to determine dennitely the origin of this new tissue but it is probable that the osteoblasts on the surtace of the trabeculæ on account of better conditions for nouri-hment have persisted and with the re establishment of the capillary blood supply are able to proliterate and re-form the bone or they might bear some relation to the tibroblasts. The process is the same in both reimplantation and autotransplantation of parts of bone or entire bones
- 5 The cortex shows an early loss of nu clear staining. Later there takes place a new formation of osseous tissue from both the periosteum and the endosteum and with a limited amount of new osseous tissue in the region of the haversian canals, the cortex is completely regenerated. Even in the transplants that are in contact with the bone of the host the new tis ue is formed independently of that sour e It seems as though this new bone is lacking in some property by which it may continue to exist and in order to endure some additional stimuli or osseous elements are nece sary to establish the premanency of the transplant This additional factor might be in the nature of certain stimulating fluids from the normal bone or an emigration of definite) seou torming cells
- o Following the first operation in the two stage autotransplantation of the epiphyscal end it a bene there i a con iderable disturbance in the function of the epiphyseal cartilage line even though the epithy is is not separated from the surrounding to sue The line of growth is most likely due to the interference with the min r va cular supply trem the diaphy 1 to the epiphy ead cartilage Viter the second operation in which the epiphy i i exparated from the surrounding the ue and the epiphy cal vessels destroyed there is a complete ce-sation of growth The lim of function occur in spite it the

fact that the transplant (united to the hot and that a part of the diaphy eal blood upply is re-estably hed. The importance of the direct vascular upply to the epiphy eal cartilage line i for ibly demon trated in this experiment

7 The vitality of the variou component of bone after tran plantation is directly r lated to the ability of that part to with stand the los of its valcular upply least dependent the part 1 upon its blood supply the greater if the positility of a luc ces tul transplintation a 1 the articular on the other hand the cartilace while more dependent the part 1 upon it vascular connection the le lik ly i the po ibility of a successful tranglantation a i epiphy-eal cartilise line

8 From these experiment and the realt in general on transplanted bone the following conclusion is offered regarding the fate of bone after tran plantation. Although each part of transplanted bone po sesses the power to regenerate independently and without the aid of neighboring bone the autonomous newly formed tissue does not pose that property which is necessary for a continued exitence and it will ultimately entirely disappear Some additional timulus is needed and uch conditions are only obtained when the tranplant is in direct contact with normal growing Therefore when there i tailure of such connection the tran planted bone at fir t shows evidence of receneration but it a 11th cient time i all med to elapse it will ultimate ly entirely disappear. However it it i united with the cut surface of normal bone it will continue to live becau e certain necessary additional stimuli and new elements will be supplied by the hot. It is possible that certain chemical or phy iplogical stimuli are supplied by the living intact bone after which the regenerated bone on account of these ad ditional factors is able to persi-t permanently Undoubtedly some definite see a clements from the bone of the ho t invade the transplant and cither repla e the temporary bone or give to it certain requirites for its perpetua Although function may play a factor in the development of bone it is not of prime importance in determining the permanence

of that tissue. The differences of comions of the various investigators is in part due to the failure to allow sufficient time to elapse before drawing final conclusions, as well as to take into account the influence of different environmental conditions on the transplant from both young and old animals.

In conclusion. I wish to extend my thanks to Professor Onhuels, of the Pathological Laboratory under whose guidance the above work was performed, for his interest and sue reations also to thank Professor Blaisdell of the Surgical Laboratory for his assistance in the operative work

Since this article was submitted for publi cation the following paper has appeared Neue Experimente zur Frage der homoplastischen Transplantationsfahigkeit des Epi physenknorpels und des Gelenkknorpels He gives the results obtained from sixteen homonlastic transplantations performed upon the upper emphysis of the radius of rabbits. He reports two successful instances one of which was not only anatomically but physiclogically efficient. He is unable to explain the variation in the results, but suggests that it might be on account of the less poisonous reaction of the body fluids. Like all expenments on the upper emphysis of the radius they are open to criticism and a careful an-

TRAUMAS OF THE BACK AND SPINE

B FRANK E. PIERCE M.D. FACS CHICAGO

N my experience with traumatic surgery I have met with no more interesting series of cases than as represented by the title of this paper, and having frequently to pass judgment upon the seriousness of such injuries, the responsibility attached there to is not always a light one. The actual conditions present are often so veiled by exaggerated imaginary or simulated symptoms that one must be very careful in making a diagnosis and prognosis not to overlook or underestimate serious injuries or to consider too senously the minor ones.

This paper is based upon the records of 758 cases Of these, 51 were under my per sonal observation while the balance are collected from my file of reports from men associated with me in railroad surgery have been in close touch with the conditions in all of the cases so reported have received frequent reports in the more serious ones have examined many of them and have been able to direct the line of treatment list includes only those injuries which have been diagnosed as a contusion or sprain, together with their complications. No cases

are included except where the period of disability has exceeded one week and I have also excluded all cases known to be combinated by a fracture or dislocation.

By a contusion we mean those direct trau mas received either over the spine itself or as more frequently happens to one side of it and involving the muscles and other soft tissues of the back. Looked upon by many as injuries of minor importance from which the victim promptly recovers they are never theless in some instances serious in character and the disability produced is an extended one.

The contusions are included with sprains because it is almost impossible at times to distinguish one from the other particularly so when the contusion has been directly over the spine. In those cases not seen by me I have a a rule accepted the diagnosis as made by the attending surgeon but my personal experience with the class of cases leads me to believe that the diagnosis has been in correct in many instance, and that cases reported as contuions are often sprains and some of the so called sprains are no more than contuing.

In confusions the trauma varies from a malerate bruing of the soft tissues to a laccration of the dorsal muscles a stretching or tearing of muscular attachments to the spine injury to spinal nerves and injury to internal organs as the kidney. In the milder cases there may be no external evidence of an injury while in more scrious ones there will be a swelling with or without discoloration and large deeply lying harmatomata may form from extravasated blood and serum Rarely a groove or depression may be felt between divided muscle bundles.

From a total of 7, cases 83 or 9 per cent wron located in the lumbar region 45 or 16 per cent in the dorsol region and 10 per cent occurred in both the dorsolumbar and sacral regions. In 62 or a little over 20 per cent the location was not specified and from the figures above it is proper to assume that a majority of these occurred below the drsal region. A period of disability in the mildest cases in thi. It averages from two to three week while a disability of from two

to three months is not at all uncommon Contusions in which recovery is more did layed and which run from four to six months or a year have some complication as sprain a possible fracture nervous ymptom or there is intent on the part of the patient to try and secure a large settlement.

A sprain may be considered a a bending or twisting of the spine and a tretching of the spinal muscles and ligaments to a point beyond their physiological range of motion (on structed and supported as it i the pine will with tand a con iderable amount of jarring and bending without vmptom injury following Its cla ticity is dependent upon the articulations between the vertebrathe intervertebral cartilaginous disc the spinal and intervertebral liga buffer ments and the spinal muscles. The clasti city and phability present lesen very mate rially the shock produced by all kinds of traumatism. The cord itself a further protected against injury by being su pended within the spinal canal covered by its layer of membranes and the cerebrospinal fluid and supported to a further extent by the The space between the dura spinal nerce and the walls of the canal tabled with loose cellular tissue and the venous inuses cord can therefore be injured only by a nar rowing of the bony canal as by fracture or dislocation by hæmorrhage within the canal or in the cord itself or produced by a shock or strain of some character. From the latter cause arises the condition described as spinal concussion a trauma defined by Dr Murphy as an impairment or loss of function of the spinal cord due to an injury which is not sufficient to produce gross anatomic changes Though denied by many surgeons I am convinced that this condition does not infre quently occur as a result of some contusions and direct sprains

Sprains are the result of either a direct or an indirect force. They occur directly as in contusions from a fall or blow and indirectly from falls upon the feet or buttocks from carrying heavy weights upon the head or shoulders from jumping slipping twi ting of the spine and from over vertion in the act of hitting pulling or pu hing

The spinal muscles are undoubtedly at fault in a large number of the cases, about So per cent as near as I have been able to estimate, while the articulations and ligaments are involved in the remaining so per cent. This relative proportion is probably due to the fact that many of the more severe somins are often complicated by a fracture and such cases are classed as fractures. The sprains have been grouped according to their ongin from direct or indirect causes, it having been found impossible to separate satisfactorily those involving only the spinal muscles from those affecting also the articulations and ligaments. One point of differentiation which cannot however be too much de pended upon is that pain upon straightening the spine indicates a muscular involvement while pain in bending the spine indicates in volvement of the luraments. Although the mobility of the spine is greatest in the cervical region where the vertebric are smallest and there is less muscular protection to them sprains occur most frequently in the lumbar region where the vertebre are larger stronger and more protected

Out of the 481 cases classed as sprain 420, or 87 per cent, were due to indirect causes and of these 200 or 47 per cent involved the dorsolumbar and lumbar region. Of 61 cases due to direct trauma, 20 or 47 per cent involved the same region. If we add to these a proportionate number of those cases in which the locality was not specified we have involving this remon 58 per cent of all the cases. Cer vical aprains the next in frequency reported but 31 times, twice as due to direct and 20 times from indirect cause contusions and apprains in the region of the coccyx were reported 20 times and a few of those developed a coccyodynia which per sisted for months. Those sprains involving the muscles alone are usually caused by lifting nulling or pushing too heavy weights carry ing loads upon the head or shoulders, or due to a sudden twisting of the body as from slipping. The ligamentous sprains are usually the result of a fall upon the feet or buttocks or upon the back and shoulders. Numerous cervical arrams have occurred in alcening cars, where as a result of sudden stopping of

a train one has been thrown up against the head board of the berth thus causing a forced flexion of the head

The symptoms in contusions and sprains are similar and as has been stated one cannot always be distinguished from the other. In the milder cases there is localized pain and tendemess with some muscular rigidity, more marked on one sale of the spine in contusions and involving both sides in sprains. In both the pain is much less when the back is kept at rest and is increased by all bending or twisting movements. There is more muscu lar modity or muscular spasm in sprains the being Nature's method of enforcing rest to the strained ligaments and articulations Some of the rigidity is voluntary from fear as has been lescribed by Page The patient assumes at all times the position which gives him the greatest relief from pain and in all attempts to rise from a sit ting position r in lying or sitting down uses the arms and less to assist in the movement while holding the back very rigid flexes of one or by th lens are usually increased. Hyperasthesias and paraesthesias are often present. Disturbances of the bowels and bladder are not infrequent in both contusions and prains. In this series 22 patients complained of increased frequency or inability to unnate and in 17 cases bloody unne was passed for from a few hours to everal days. Lighteen ases involving the lumbar and lumbosacrai regions complained of particular pain over one of the sacro-iliac articulations.

Contusions and sprains are frequently so complicated by other symptoms of nervou disorder paralyses, etc that our chief concern may be regarding the complication rather than injury itself. In the series 27 cases developed a traumatic neurosis 3 level-pped hysterical paralyses one a traumatic spondyhtis and an epileptic consultant son occurred in one case one mith after an injury to the back though the previous history was entirely negative. Eleven cases were classed as malingerers. Two cases suffered from harmorrhage one extradural and the other within the cord as a result of strain due to lifting.

The period of disability in sprains averages

longer than with the contusions. The muscular sprains are usually recovered in from two to three weels. The milder ligamentous sprains disable one from four to six or eight weeks while the severe type will average from four to six months. In some cases jiam is present off and on for several years. Those complicated by a traumatic neurosis average from six months to a year or longer.

In making a diagno is great care should be taken not to overlook a more serious injury as a fracture or di location. This has been done in a number of case of which I have record \ ray plates must be obtained in all doubtful cases and these will at times show a fracture or other lesion which cannot be positively demonstrated in any other way Owing to the great danger in handling a patient suffering from fracture or dislocation we mu t exercise great care in conducting the examinati n \ valuable point in differen trating prains from dislocations particularly in the cervi al region is that in sprains all the n rm il mexement, can be obtained though very painful while with a dislocation certain movements are not possible but the effort to make them is not particularly painful I or this reason all manipulative movements hould guard against the danger of inflicting more damage to the cord structure in case a dislocation or fracture is present. The necessity of such care is emphasized by a case reported to me several years ago as a sprain of the back Several days after receiving the report a supplemental report stated that upon attempting to turn the patient upon his ide in order to make a more careful examination a sudden marked detorraity occurred due to a fracture dislocation at the level of the seventh dorsal vertebra No difficulty hould be met with in diagnosing the relinity enturing or prain but many errors are made in separating the muscular from the ligament sus sprains

The promo 1 depends upon the actual mury u tained and the complications which are. The period of disability is no true index to the secenty of the injury and nervou symptoms may be present in minor as well a severe cases. One must ever be n the likkut for malingerers or damage.

seekers. The settlement of a claim for dimage often has a most benchical poschie etc. to upon a patient and recovery takes place rapidly though there may be nothing in the case to suggest an intentional exaggeration of symptoms.

I shall make no attempt to describe treat ment of these cases in detail. Contusions should be treated the same a when they oc cur in other regions. In general the treat ment of sprains depends upon whether the muscles are at fault r if the ligaments and articulations are also involved. These cases in which the muscles ilone are affected should be given rest for a few days followed by mas sage and a gradually increasing amount of gymnastic or setting up exercises. The ligamentous si rains require rest and the spine should be supported by adhesive strapping or other more effective means to secure this Except for pain and tenderness at first massage and moderate exerci e of a strained muscle or group of muscles should give relief but if after such a treatment the pain is in creased and no temporary relief is felt then we should assume that the ligaments are in volved and treat accordingly. Complications should be treated according to their symptoms Lavaronment sympathy of triends and members of the family visions of perma nent disability or invalidism, business wormes etc. all tend to bring on or increase nervous symptoms and thus delay recovery

ILLUSTRATIVE CASES

Spinal concuss on Case I L J G switch man injured December 2 1003 account of being thrown from the top of a box car to the ground and striking upon the back and right shoulder Was unconscious for five to ten minutes. When we will be to use the right arm and could not move either leg. Sensa tuon not disturbed and reflexes present but slight Iy exaggerated. Slight motion returned in legs in a few days and by January II 1904 he was able to return to work.

CASE J G switchman age 48 mjured April 77 foro On account of d fecti e grab from he fell from the side of a box car to the ground striking upon the ba k symptoms as reported were a motor and sensory paralysis of the arms and all below the level of the first dorsal vertebra. A report of Vlay 1 stated there was a little return of motion in one hand and returning a maxion in the other also a little motion in the legs?

The reflectes were also returning alowly Bladder and rectum still completely paralyzed. Three Large plates were all negative as t fracture Diagnosis mad was hemorrhage into the cord cervical regim followed by transverse myellits and due to severe spinal concussion. The patient died high 70 tops

In speaking of isolated injuries to the cord without injury to the spine, Leytlen states that from concussion a paralysis may follow at once or soon and may be fatal. The cord shows itself to be lacerated together with free hæmorrhage or extravasation of blood in the vertebral canal or it may show no grow or microscopical changes. The real changes he states, are probably a direct traumatic necrosis of axis cylinders. If a patient lives recovery may follow quickly but in all cases where an effusion of blood has occurred a chronic myelitis is to be feared

C tanes with for a Case 3 H R W brakeman single, age of injured March 903 While standing in the open doo of a boggage car be fell backward out of the car and struck upon wood rail protecting some signal wires H was taken home and I saw him within the next hour o two He had a severe to tunion wer th region of the left kidney and was sufficient from intense pain in the back. The first surice passed following the injury contained a considerable amount of blood and continued it contain blood fo several days after which it became clear He returned t won about ax weeks, but pain continued off and on fo

a number of years. CASE 4 M C laborer age 35 injured August o, 900, account of falling from a gravel car to ground and landing upon his back. He was taken to the hospital by ambulance and remained in the hospital under my care up to April o oo then was kept under observation until May amination showed contumons all along the back and spine. Pain was most severe in the muscles on the left side. Hyperesthesia present from the mid dor sel region d waward. There was a spestic parely sis in both legs, more particularly the left, and a marked increase in all the reflexes. No bowel or bladder disturbance was present Improvement was very slow but more in the right than left leg On January 20 examination of right leg showed muscular speaticity still present refleves exaggerated but ankl clonus diminishing no Babinsky sensa-tion nearly ormal. The left leg showed more muscular spasticity and very much diminished voluntary movements of the leg due largely I felt to fear of increasing pain in the back. All bending movements of the spine were vokiled as m ch as possible. \ \text{ray plates were negativ} \ \text{Not entire} ly satisfied with the slow recovery and fearing that

a more se ere mjury had been verfooked I had bim examined by D. J. B. Murphy on February 13 and my diagnosis of continuous: (the back with some pyrain was continuous of the back with some myrain was continued. Our line of irratiment was unchanged but the similarition was followed by more rapid ex very than at any other time due to the mproved me tal condution (the patient. With the added warra e that in serious injury was present be mad in re. If it is get around and soon found that the increased activity did not increase his pain b t rather lessened it. CAR 1 A. E. I. merchant ago 35 injured February 2 10.3 Claimed to have been jring in berth when sudden stop of train three him up against head of berth, cunling to tusion of head and sprals of muscles of neck. A neurologist in Cleve land who examined him the day of the injury found no motor occurred visitual than the sum of the man stated be felt all right until some hours after the Injury. Subsequently be was examined by seven or eight prominent surgeons and neurologists on account of plain into neck and the neural nervous symptoms found in a traumatic neurous. In all cases the diagnosist was the same. This man wa still complaining for more than a year following indury.

Hall garry Case O W helper injured September so 1909 by falling into a prt. Was picked up unconscious. He austained a severe contusion i the spine over the upper donal region. Confined to hospital up t October 22 A report under dat of Normeber 1 stated that the marwhiled well with use of a cane for two weeks after be left the hospital then began using crutches and complained very much of poin in the back. The case was settled abortly afterward and four days later th man discarded his crutches and desired to resume work. CASE 3 T E L conduct 1 age 43 infured

CASE 3 T E L conduct r age 43 injured april, 2 o 3 through fall from the top of a car to the ground. He complained f pan in lumber region, b to mark of lajny was found pomeann leason. He consulted everal different physicians considered to the second party of the case where the complex second party of the case was either a poorly instructed malingerer r be might have a trummite curous with marked exaggration of signs and sympt ms. This case was settled, and immediately after the man went on a drunk the case was settled, and

lasting three days

ABDOMINAL PREGNANCY

B BETHEL SOLOMONS, M.D. FROPI D. IN IRREAND Oracidized to Morsey Benefal Extractory Market Roughly Herotal

ABDOMINAL pregnancy which may be defined as the development and growth of the fectus in the abdominal cavity may be either primary or secondary. The fact that primary abdominal pregnancy may occur is denied by some authorities although Parvin (1) gives Rielmwachter's explanations of its occurrence as follows:

1 The ovisic may rupture so far from the ampulla that the current caused by the move ment of the clin cannot carry the ovule into the tube.

2 A temporary abnormal position or movement of the abdominal organs may obstruct the passage of the ovum.

3 The end of the tube may be completely closed in consequence of former inflammation, and the ovule be impregnated by semen coming through the other tube.

4 The tubal ornice may be so narrow that while permitting spermatozoa to pass, the ovule enlarged by impregnation cannot pass.

5 The tube may have lost its cilia from disease and the current fail so that the ovule is not carried to the tube 6 Old exudations or pseudomembranes may either obstruct the onfice of the tube, or be in the way of the oxylle reaching the orifice.

7 Abdominal pregnancy may occur when both tubes are normal. The ovule impregnated at one tube may pass out into the abdominal cavity and then cross to the other tube but the latter will not admit it because meantime the ovum has become too large.

This last is certainly a most ingentous explanation The condition may also arise from an ovum escaping through the scar following a casarean operation or through the fistula in the cicatrux of a cervix remaining after the performance of subtotal hysterectomy With all these possible explanations it seems difficult to exclude the occurrence of a primary abdom inal pregnancy. There are very few definite cases reported Among them those of Béhier (2) and Calloway (3) bear close investigation. Many experimenters on animals prove from their experiences that primary abdominal pregnancy is to be considered a very possible occurrence Blair Bell (4) con cludes that because it is common in a rabbit

anisthetic, I asked Dr Glenn, consulting groccologist to the bospital, to see the case with me. If agreed it was impossible t diagnose definit by that there was some marked absormality and that the best policy was t open the abdomen.

To touch on these diagnostic points of the case in comparison with those points which I was bl t

gather from my study of the subject.

1 Sensit! oness was present though not extreme intermittent contractions were not notice able. This does not seem to be a very distinguishable sign for while these contractions are valuable diagnostic points when present their bacned does not contra-indicate pregnancy.

3 There was marked irregularity of outline 4 The child was not directly under the skin

5 Heart-sounds were not directly under ear

6 Retroversion was present

On J mary 8.1 opened the abdomen by medal incidion from the sympleys is t to inches above the umbilicus. A tumor bemorthagic in poemance stretching a little beyond the umbilicus was seen. In separating the adhesions of the tumor which were numerous and were chefity to the intestines, omentum, posteri pelvi will and terus, in the left life region the finger entered the sac and

fresh fortal foot was extruded. There was some old blood on the right side and there was m ch fresh hemorrhage from the separated parts of the sac. It was necessary to remove and ti -off oment m in several places while the rectum for two r three inches required oversewing where the placent was removed There were several pieces of tissue removed during the operation which consisted possibly of som kind of sac. While the operation w in progress the patient was given saline submammary pitultary extract 1 ccm. strychnine sulphate, gr /3 etc. When the fortus and placents had been re moved it was apparent that the right t be had been taken wyl the mam. The trus left tube and both ovaries were left sit The diagnostic difficulty was here made apparent for the uterus lying retroverted without retroflexion was prac tically imbedded in the t m r which filled the pelvis. It was impossible to i vestigate further for the patient was m ch blanched, was pulseless t ne period f the operation and it was necessary t close the bdomen as quickly as possible and t get the woman t bed where continus rectal saline and other usual restorative measures were carried out On the sixth day cystitis developed which persisted for seven days. On the fourteenth day she passed per rectum wash leatherlik piece of material which D Wigham reported t be cast of the rectum This phenomen was marked proof f the britation to which the box 1 had bee The long abdominal wound heated by first intention and she was discharged from the hospital in good health on the twenty-with day

The history of the treatment of abdominal pregnancy is interesting. Firstly, there were the days when the condition was always found post mortem. Next when treatment was postponed until after the death of the child (10) or when the child was removed and the placenta left (20 21 22). In those days gynecologists were vying with each other to ind the best infanticide. Barnes (23) injected into the sac atropine and strychnine. Fined rich (24) morphine while Thomas, (25) and many others were using the electric current. Barnes inoculated the mother with syphilis to kill the child. Generally speaking the results of these measures were disappointing

The pathological report does not throw much light on the subject. The specimen consisted of a 5 to 6 months fresh foctus and placenta. On the maternal surface of the placenta is seen an area which on microscop ical examination proved to be blood-clot and which probably is the place where it was im planted on the rectum. Sections from various sites showed nothing abnormal A search was made for tubal tasue but none could be demonstrated Much omentum was removed and a microscopical examination of portions of this failed to show the presence of decidual cells. Outerbridge (+6) has proved that decidua like cells are found in the omentum in cases of intrauterine pregnancy This has been noted by Schmorl (27) Kinishita (28) and Shaviodskindis (20) They have also been found on the peritoneum covering the posterior surface of the uterus the anterior wall of the rectum in the appendix (30) in a parovarian cvst (31) and in the varina (32) It is strunge that in my case there was no decidual reaction in the omentum removed

The most probable explanation of the case is as follows: That there was a very slight rupture of the tube at 2 to 3 months that the orum remained attached partially to the tube and that as it grew the placenta attached itself to rectum omentum, and posterior pelvic wall etc. that this caused irritation which predisposed to a connective tissue prolifers too thus surrounding it with a wasular sac. The patient evidently sought Dr. Ryans opinion shortly before the time I first saw her on account of the pain caused by the enveloping sac which was much stretched this latter fact was clearly demonstrated during the

operation. If no operation had been per formed what would have been the result? She might have progressed to full term might have shown symptoms of distress earlier (ases are on record where the dead to tus has been carried for many years in the abdomen Heiskell (33) reports a case of 40 vears duration. In the present case it seems most probable that hamorrhage or other dan gerous symptoms would have appeared soon

The following are important points in connection with abdominal pregnancy

The fact that the cause of abdominal programs has not been definitely established

2. The extreme difficulty in definite diag nosi

2 From a review of the literature and of my own case (though not wishing to argue from one experience) the rational treatment seem to be to remove feetus and placenta and to too the hemorrhage. This hamorrhage can be topped therefore it is bad policy to leave the placenta in situ

INTERPRETATION OF THE DIAPHRAGM AND DEXTROCARDIA

WITH A CASE REPORT

в и с поор лр (rn Ingres

CASE of diaphragmatic eventration and associated dextrocardia har re cently come to my notice. Thus condition a I feel of sufficient ranty to make its publication desirable

Apparently eventration was first described and named by J L Petit when he reported a case in 1700 This term has been in comm nuse ever since. In 1912 in his paper on Diaphragmatic Hernia (1) Dr H / Giffin pointed out the fact that the term eventration would apply equally well or even better to a true diaphragmatic hernia in the commonly accepted sense By reason of its common acceptance however the term eventration has been continued in this article. In sup-

port of Petit's nomenclature it may be stated that he believed the case he reported to be one form of true diaphragmatic hernia

In the recent Figlish literature on the ubject the most extensive article is one by Sailer and Rhem (2) and to this paper I am indebted for most of the cases mentioned Since 190 the Index Medicus lists only a hort brief of an article by Dr. Hermann Fi her (3) under the title Relaxation of the Diaphragm. He reported a case

In all about 500 cases of hernia and even tration have been reported but Fischer was able to find only twenty three of eventration and Sailer and Rhein in 1905, could collect only twelve definite cases besides their own though there were several discarded because of insufficient data

obragm and d virocardia (see rad ographs)

We may safely assume that the condition is very much less common than duphragmatic hermin with which it is most apt to be confused. Fischer defined eventration as a thinning out and fatty degeneration of the muscular fibers of the diaphragm and bulging upward of the same to the level of the second or third rib. Safer and Rhein detine it as an abnormally high position of the left half of the diaphragm with dislocation upward of the andominal viscera especially of the stomach with hypoplasia of the left lung and dislocation of the heart to the right.

The etsology is uncertain

Some writers consider it as a true hernia
Others believe that it is secondary to

hypoplassa of the lung

3 It is considered also the result of dextrocardia.

4. Some think it is due to a primary con genital defect of the diaphragm.

5 Again, it is regarded as a result of acquired lesions.

Of the 13 cases reported in 1905 1 was found in a foctus one in a newborn baby and 11 In patients ranging in age from 19 to 75 years of age. On these cases there were twelve post mortems and one patient was still lying. Two of the cases died of peritonitis, one of pneumonia 1 of typhoid and 1 of a carcinoma of the tongue. In at least 6 the condition was f und accidentally at post mortem. Two asses were reported as destro-cardia Apparently an abnormal condition of the diaphragm was suspected un only four or five

The clinical symptoms were very irregular. One patient complained of asthmatic attacks, releved by eating one of vomiting and gastric disturbance and one had himateness and from the symptoms an incurrented disphragmatic herma was suspected and an operation performed at which time an eventration was found.

I have also seen a case of intestinal fistula of the left thorax, in which the patient had been operated upon under the supposition that an empyema was being dealt with and instead of which there was a true diaphragmatic hernia.

One case is reported in which the symptoms appeared after pneumonia. In one case an adult male after a severe shock there was a sense of something giving way followed by cough dyspaces and pain in left chest. At thost mortem an eventration was found.

Fischer also mentions a case in which the condition seemed to develop following pneu monta and after a time cleared up. Here a disgnoss of paralysis of the left phreme waters was made. Sailer and Rhem believe it is the result of a hypoplasia of the left lung together with a hypoplasia of the left lung of the diaphragm. The majority of cases are undoubtedly congenital and this hypothesis is true in many cases.

In some however that appear to be congenital in origin there is no hypoplasia of the left lung. In others, again there appears to be a definite association of eventration with an acute infection and in some cases there is found a diffuse faity infiltration or a fatty degeneration of the muscular fibers of the disphragm. In one of the cases men tioned and in the one I report, there seems

a letinite relati n t traumati m Unluftelly the valt marity it ases are In the nienital lefe to the haphragm r lest ung r i both Other n litten mati be nifted a it appear that our intection traumation and injury t the left thrent nerve at scall nally an Insluitr

The see here reported to pecual interest a the line all finding and the hit ry rreva u trauma w ul l lead ne t u pect that he was dealing with a drachragmatic hernia. In fact with ut the radi graphic under. It is thelieve that a diament to eventration could be made. The chief difnulty i alway in fitingui hing between n littion It i also tated that pneum, the rax cavitation of lett lower lobe and ubdiar bragmati its neumoth rax mu t be interentiated. I d in threel that the latter nditi n tier much diagno tie difficults

A r neum thorax h uld present charac teri ti phy ical ninling and there will be bulein is the interestal page, and immsbility i the left thorax while in eventration or hernia the respirat ry m vement appear n rmal

It is not concervable that cavitation of um ient extent to be mi taken for eventra tin uld exit with ut a previou, hi tory and unicient clinical evidence of pulmonary lisease t make the diagnon clear Both t the above condition could at once be pentively hagmised also by a radio-copic examinati n Subdiaphragmatic pyopneu m th rax 1 also tated to be a condition to be it tingui hed. I have seen one case a well a several 1 ubdiaphraematic abscess and in n ne 1 them was the polibility of even trati n r herma considered. These generally r ult ir n a rupture of diseased gall bladder r the pert ration of a galtric or duodenal ul er. They also are near smally the result t inte ti n following abdominal operation The hit ry if the case together with the lemmite evi lences of sep is present should be umcient t exclude eventration or hernia

The ne condition that offer serious dif n ulty in lifferentiating from eventration i haphra matic hernia. These condition may ir sent i lentical clinical manifestations and

an be lifferentiated fils by a are u ali e die rituer se di examinati n. In m. in tances a radionram radiurs examination will satisfact my lifer r trate the two though a rinally a compina tin t the tw meth 1 u 1 le ne es and In the present in tance the fir t plate i ufficient to lear the liam of O a challs h wever the air bubble in the upper par the toma h lead to a talse line appearing bel wit which has been mitaken in th diaphragm and because tithi a mi-taken hagne to therma i made. The me take an be as ided by filling the it mach with barrum wlute n and taking a tlate with the patient hip umciently elevated to fill the ardiac porti n and i ree the air bubble t the pyline end. The ame result an beattained by fluor soon examination after myrns barrum and palpatin, the abd men so a to the roughly fill the cardiac ports in at the t mach

Another important diagn, tic point i the tact that in hernia there i nyation it the diaphragm and in eventration the re-piratory excurion appear normal. The i best determined by the flu rocode In the present case there is normal mobility of the diaphragm | Vlack of movement would also be found in eventration resulting from a phrenic paraly 1 and the a sociation of an eventration with a fixed diaphragm, hould uggest the latter condition

The extreme importance of differentiating between eventration and diaphragmatic hernia is due to the fact that hernia is a urrical condition and operation i followed by good result, while eventration is not so con idered

In this connection a point of much theoretical interest i. What would be the result ot a plication of the diaphraem Such an operation hould be attended by no greater rik than the operation for herma. The re-ult would be dependent upon the ability of the diaphragm to with tand the increaled abdominal pres ure. It is nos ible of course that this would lead to a further tretching of it, attachment, and a recurrence of the condition. The point could possibly be cleared up by an experimental plication if the diaphragm in dogs though it is questionable whether an experimental eventration could be produced by section of the phrenic nerve. Unless such an artificial eventration could be produced before plication the experimental proof would not be conclusive

Many cases of eventration suffer little discomfort, and of course in such the risk of operation is not warranted. If however the condition is attended with sufficient symptoms to interfere senously with the patient's physical well being I believe that a plication is a procedure to be senously

considered In conclusion it may be stated that-

Eventration is attended by no definite train of symptoms, and is in fact often symptomiess, though it is probable that a careful investigation of a series of cases would show that they were all below par physically as in the case reported

2 That it results from congenital defects in the left half of the draphrogm or the left lung or of both. That a small percentage of cases are undoubtedly the result of trauma. or follow acute infections, as a result of de generation of the muscle fibers of the diaphraem or injury to the phrenic nerve

That the physical findings are often identical with those of hernia, and a differential diagnosis can be made satisfactorily only by means of radioscopic examination though a history of sudden onset of amptoms fol lowing injury is very suggestive of diaphrag matic hernia, rather than eventration

That the most important and only uniform physical findings are heart duliness to the right of the sternum tympony on percussion and gurrling heard over the precordial area These symptoms are the

same in hernia and eventration

s Rupture with bernia of the diaphraem is undoubtedly much more common than eventration but it is probable that more cases of eventration are being overlooked than in the former condition because of lack of symptoms and also because of the fact that hernia is generally associated with severe trauma and severe physical disability which often ends in death and the condition is found at post morters. In cases that do not die the resulting disability and history are more apt to direct attention to the condition present than in eventration

6 The finding of dextrocardia should always call for a careful examination to

exclude the possibility of eventration

GANGLIONEUROMA

B RICHARD I BERIAN M.D PHYRIPPERGE

ECAUSE of its great ranty and the paucity of information in the English literature a brief review of the known facts concerning neuroma seems to be of value \euroma is seldom diagnosed before operation. This frequently is due to a lack of knowledge on the part of the surgeon as to the prevalence of this tumor Perhaps if knowledge in regard to it were more gen eral and slightly greater care were exercised in diagnosis, we would find the tumor to be much more common than is supposed

At first, the peculiar white glistening encapsulated tumors found in close relation to the adrenals and the sympathetic nervecords were thought to be surcomata by the American and English observers (Dalton, Pitt, Orr Parker Pepper Amberg Richards Hutchinson, Tileston and Wohlbach) were supposed by some to arise in the supra renals Kuster however found that the intercellular substance was fibrillary and did not stain the same as the intercellular substance of sarcoma but did give the same stain

ng reaction a glia so because of the peculiar osettes imilar to those found in glioma and hi characteri tic taining reaction he grouped hi tumors a gliomata

While most of the author agreed that the umors were composed of nerve-tis us there following the publication of Ku ters va paper considerable discus ion between Eu opean pathologists at to the origin of these umors Finally J H Wright ettled the controversy by proving definitely that they were of sympathetic germ-cell origin Wright called these tumor neuroblastomata accounted for their presence in variou loca tions by the accepted tea hing that nerve cell not differentiated have a tendency to wander out of the embryonic nervous system and form not only nerves and ganglia but also the components of the sympathetic nerv ou s tem

However it wa Tick and Bielschowsky who is t prominently empha ized the close relation, hip between these tumors and sympathetic nerve-element. They named them ympathoblastomata or embryonic sympathetic ganelomata.

According to Poll this relationship of the tumors to the sympathetic may be dia grammatically shown in the following outline

Funor are known con.isting of one or all types (except the pharochromblasten) of the above cells. These tumor in turn are but a ubdivition of that great class of tumors illed neuromata.

Neuroma which a general name for the entire class of the tumors under discusion a livided into (a) true and (b) false

The true neuroma is derived from pecine nerve tissue, and is the result of hyperplacia of ganglion cells or of the new formation of ginglia. The talse is not a neuroma, at all but i rither a sare ma in a fibroma.

According to Pick and Bitlsch wky a neuroma con ist of nerve-cell originating either from the ympathetic nervou x tem or the cerebrospinal nerves and gangha. When the glas fix-ue i in dundance it i poken of a a glioneuroma. Under the latter are included (i) pure celled neurox toma of the cerebrospinal ganghi (Marchand) (i) ganghoma embryonic ympatheticum (i) large celled form of the area of the Tuberosen Hirisklerosa. (4) neurinome (Verocax). The relation, hip of the different classes of nerve-celement tumor i hown in the accom

The first ganglioneuroma wa described by Loretz in 18,0 It occurred in an epileptic 35 years of age and was found on the left side of the second and third thoracic vertebra. It was an egg-shaped smooth hard tumor which evidently arose from the sympathetic On autopsy however no communication with the sympathetic was observed It is probable that Loretz did not recognize the definite relation hip of his tumor to the nerve-cla ments although he described the tumor a consisting of two layers (a) the outer dense of connective to ue (b) the inner soft consiting of numerous ganglion cell partly separate and partly grouped

In tructure the ganglioneuroma is alveolar in type with septa of connective ti-ues separating various sized masses of cells poor in protoplasm but containing nuclei rich in chromatin. In some cases these collections have a rosette form and the cells are separated by a fine fibril intercellular substance. This intercellular fibrillary substance as is shown by Pick has its origin in the cells, several of the fibrils having been traced to individual cells. The more the fibrils and the cells become differentiated the closar will be the resemblance to tumors of glia, and then of fully differentiated nerves the neurothroma.

The following varieties of tumors have

been described

a The sympothoblasten (Marchand and Hecht)

b The group containing bundles of fine fibrils separating the cells (I ick Landau)

c The combination of the fibril masses with ganglion cells and nerve fibers (Martius) d The ganglion cells with nerve-fibers.

If the intercellular substance is not mark edly hbrillary, then the tumor resembles a small round-celled sarcoma and so it fre quently happens that the tumor in the neigh borhood of the kidney which has little intercellular substance is mistaken for a sarcoma.

In the tumor mass, small cells similar to lymphocytes are seen in conjunction with very large cells. These small cells are (according to the views of Wright Landau Marchandetc) the immature ganglion cells which later develop into the larger cells.

Vascularity The tumor as a rule has but slight vascularity so that it may be removed

with but slight bleeding

Location Ganglioneuromata seem especially irequent in the lumbar region where the originate from the embryone cells of the suprarenal body. As is known the chromatin substance of this body is of sympathetic origin so that reasoning from analogy we would expect to find tumors of ganglion cells in locations where the ganglion cells are abundant and have a tradency to become highly differentiated and specialized. This we do They are found originating from the sympathetic ganglia (Landau Pick) also from the sympathetic cords (Shilder Landau) in the cocycegal gland (Alexais Imbert)

According to Friedrich ganglioneuromata are most numerous in the sympathetic cords and ganglin of the abdominal cavity \extra ere the sympathetic ganglia and the medulla of the sympathetic ganglia and the medulla of the sympathetic ganglia.

They also have been found in the brain (Schminke Pick and Bielschowsky) in the cord (Pick) in the dura mater at the superior orbital fissure (Haenel) in the gamerian ganglion (Marchand and Risel) in the retrobulbar part of the optic (Perlo) in the cansule of the kner (Haenehach)

In sidence Ganglioneuroma Is more fre quent on the left side of the body than on the right 13 out of 16 cases. As a rule it is only a solitary tumor however in some instances metastases have occurred and in one case Henecke found more than 160 tumor nodules. In another case (Miller) metastases were found in the neighboring lymph glands and in another metastases were found in the hiver (Jakolsthab)

Ganghoneuroma is more frequent in women than in men (63 per cent) and in the first 20 years of life. The following is a summary of the age in process.

t years	\$ cauca
to so years	Q CRACE
not poyears	4 CHACS
pot 4) calco	6 0250
40 t 50 years	CRM
Over so cars	4 CRUCE
The above the second state of the second	75

The oldest as 76 years (Welchselbaum). The youngest as 3 months (Busse and Γ bets)

Symptoms There are few if any clinical symptoms of ganglioneuroma the tumor being most frequently discovered on autoosy after the patient has died of some other However in many instances the turnor mass has produced symptoms by pressure on the neighboring organs and nerve trunks. In one case (Williamson s) the tumor was located on the sacram and caused dyamenorrhora-at the same time the uterus was displaced and anteflexed In a case of Busse the tumor tilled the entire pelvis and reached to the margin of the ribs, so that involuntary passage of faces and urine occurred. Most of the tumor except a small piece under the ribs was removed In tive years there was no return. In th case of Braun, the north was torn during the

lg (tl(t) (next th (memoral)

remov d of a large abdominal ganghoneuroma which was supplied by four large arteries from the aorta. The aorta was resectioned the two ends united, and uneventful recovery on used. In a case reported by Peters the tumor had pressed the kidney upward.

In the three cases in which post operative collapse occurred Cel ner believed that a sympathetic book with a vessel paralysis had occurred with a consequent bleeding into the abdominal ven

F pecially characteritic of ganghonduro mare the congenital origin the occurrence in very early life, and the variation in malignance. It generally occur is a single tumor although multiple tumors have been described by Kniuss. Kredel Beneke, and Risel.

Prognoser As a rule there is little tendency than the wonger the individual the greater is the tendency. The malignancy seems to be reduced in those cases which show a great viriety of cellular elements. The greater the tendency to infiltrate and the less the different virient of the cell the greater is the malignancy. Metastases may occur in neighboring lymph glunds or in the liver (Jakobsthals)

Freilment The only treatment is free and a mplete removal. If the entire massinn to be removed without danger to the patient a much as possible should be cut that Cures conclumes follow such removals.

My use of ganglioneuroma was referred to m by Dr. H. Th. pati nt wis a will nourished final infant of 10 months. The chief complaint was a swelling in the left lumbar region whi h appeared ix months previou and followed () erysipelas. The infant was otherwise normal.

The mass was seen to vary in position during respiration becoming more promined during impiration and less prominent luring expiration. On publication the mass was lethnable as a tumor about the aixe of a small apple could be pushed up under the ribs, and was not tender or clastic. On crying the mass was again jushed down. The vertebre were apparently normal no kyphosis or scoliosis and no tent mess. The abdomen appar ently was normal.

Diagnostic remarks From the history and physi al findings it was extremely liffcult to make a diagnosi. The most probable hypotheses were that the mass was eith r a lumbar abscess connected with the kidney or a tumor of the kidney itself In view of the rarity of tumors in the adrenal or of the ki lney (with the exception of the cystic degin eration) in children we naturally were inclined to think more of the possibility of an encapsulated abscess. I uncture was made into the mass and only a very minute quantity of straw-colored fluid was removed Examination listlesed some amorphous crystals. This result rendered rather more vague and indefinite the hagnestic conclusions so that the patient was finally referred for operation with the diagnosis of lumbar tumor probably connected with the kidney

Operation May 11 1015 Fth r angesthesia Incuson three unches long and parallel to an I three fourths inch from the last nho on the I ft as Je Incusion was made through the latissamus dorst an I subjected facta a small nodular mass present I through an opening between the quadratus lumborum and the aldominal muscles. tendon from its attachment is by far the most common and results only in partial disability to the limb An important factor associated with this condition and one which would seem to be the chief cause of the pain and discomfort experienced in many of these in complete cases of avulsion lies in the trauma tlam to the bursa overlying the tubercle This bursa I have found at operation enlarged and tensely distended with bursal fluid Pressure over this tense bursa before opening always produces pain accompanied at times by a slight increase of local heat as is assocusted with bursitis. This tenderness lasts longer than would be experienced from the simple rupture of tendon fibers or the senara. tion in continuity of a portion of the tubercle Then again the local swelling is greater and persists longer than would be looked for in such a trauma. So it would seem from these findings that a low grade inflammation of this burna is produced kept up by the attempted use of the hmb until the fixation of the ruptured tibers is had the contractlyn of the quadriceps stopped or the ankylosis of the fractured tibual tubercle to the tibia completed

The consensus of the findings in these cases as to recover, from the injury places the time from az months to two years. If the milder degree of damage has taken place and the diagnosis is made shortly after the injury a few weeks of local treatment suffices.

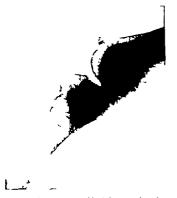

such as hang the leg in extension with strong compression over the tubercle by crossed adhesive strapping. In the most severe cases where partial or complete fracture of the tubercle has taken place and in cases of late diagnosis symptoms of pain tendernes and partial disability having pensisted for saveral week or months, or in spite of local treat ment then more radical measures should be treated to the contract of the contr

CYLINDROMA OF THE TONGUE

WITH A REPORT OF TWO CASES

B ROBERT II BAKER A B A Agrow Micro

\ \ LINDROMA characterized by hva line formations of typical arrange ment has been described in the text books as having the following clinical characteristics It is located about the head especially about the orbit, the salivary glands nose antrum of Highmore and the mucous membranes of the cheek and gums. Its growth is slow recurrences are frequent but there are no metastases. Except for some forms described that seem to include a distinctly succomptons element the tumor seems to be relatively benign fusion exists from the fact that some quite different tumor forms have displayed some of the same hyaline characteristics, and also because of the lack of agreement in defining the term cylindroma and endothelioma

Several cases that may be described under the title cylindroma have been discussed in the hterature. In general the majority of bservers have classed the growth as an endothelial form of connective tissue tumor. Some difference of opinion exists even on this point. some men choosing to explain the hvaline structure to be described later as a produ t of mature connective-tissue element like Lubarsch () believe the form originates not from the endothelial but from the penthelal cells of the blood and lymph vessel The most widely hald or inion is howe er that the tumor is an overgrowth | f en lothe lium hung lymph and blood vessel and that the hyaline so generally described in ther a deg meration product or a secretion product of these cells. This latter point ha not been so widely discussed

In 1919 Dr Oberlin (2) In a concise and thorough review i the cylindroms, questioner reported three cases from this laborator, which he lescribed a cylindromata. In that report she considered all the literature to date stating the prevailing theories of origin development and classification of the relatively rare form. Two of the three cases which she reports came from the head with a history of 15 to 30 vers growth. These she describes as endothellomata. The third case from the uterus, of rapid growth, exhibits a mixed type with a sarcomatous element. In 1914, Baumgartner (3) in discussing lapothogenie dis evilundrome takes this view that the cylindroma is a mixed tumor constaing of epithelial and mucoid elements existing side by side and with a predominance of the mucoid material. A further discussion of his views will be considered later in this report.

The especial interest attached to the two cases in hand is the fact that in all cases described in the literature to date none has been mentioned as coming from the tongue Both tumors were received at the Pathological Laboratory of the University of Michigan within a period of less than two months and present nearly identical features

Case r (4) must be discussed only in the light f it micruscol ral appearance as no hi tors was obtainable. Case r (5) occurred in a woman age to Two years previous it began a a thi kening in the right dorsum of the tingue. It grew slowly until about three month, before removal at which time it became painful and grew more rapidly. You also paths occurred with the growth and it was removed entire with temporal.

In the gross Case I appeared somewhat balobed with a dumens not about eight milli-maters in its two smaller humeters and twelve in its greatest humenson. Case 2 was some what larg r and ensited as a single mass Neith r of the tumors was received in fresh en ugh state to express the hvaline tubes as has been described by some authors. Both tumors gave the hyaine glas v appearance usually described in the section of such growths the descriptive name. Vindroma coming obvious ly from the appearance of the

hyaline exlinder and ball on section in the gross

Microconically the pecinicus present the following teatures Enclosed within a thin but quite definite connective tissue cap ule within the muscle of the tongue is to be seen the characteristic arrangement of curved and twisted hyaline strands which in serial section would form the cylinders and knob described in the gross. In some part of the tumor the hyaline patches are seen to include small nests and cords of cells which appear to be of the endothelial type—flat with rounded and ellipsoidal nucleii contain ing in some apparently the most recently formed cells a rather limited amount of chromatin material. These cells vary quite markedly in ize averaging somewhat larger than the endothelial cells lining normal lymph paces. The same type of cells is noticed in greater abundance arranged in nests and cords extending between the hyaline cylinders The somewhat radial arrangement of these cells in reference to the hyaline cords is due I believe to contriction of the latter sub-A noteworthy feature is that the hyaline areas are almost exclusively bounded by these cell suggesting the origin of the hyaline. A much less con picuous element the mature connective tissue cell which with some small blood and lymph vessels serves to make up the rest of the tumor Special staining by Kresyl Echt Violett gives no staining reaction for amyloid or mucin I an Green tain gives the deep rose red reaction characteristic of connective-tissue hyaline to the non-cellular glassy material and no reaction for mucin is obtainable

Under higher magnification certain quite h tince marking within the hvalue material urgest the nuttine of large flat cells from which the nucleu has degenerated. This conception i further substantiated by finding, here and there a definite cell inclusion within the hvaline howing the complete cell authine but with the pace vacuolated and is intracted pixhoric nucleus at one side. By careful search uch cell are seen in all tages of disintegration even to the point where the nucleu ha lost its contour and nly a remnant of chromatin remain within

a cell boundary. The same cell may have an imperfect wall and may enclose what appears to be a beginning infiltration with the haline which I as unit to be a secretion within or other cell about it.

The connective it we element in both th tumors at hand how a marked hyaline degeneration but it is quite impossible to trace the relation of this ti we to the hyaline of the cord. The tumor how some mult blood vessels with markedly selective wall, whill others farther removed from the hyaline evinders are quite normal in appearance. On of these tumors present a somewhat different which I interpret as representing a vanite stage of the growth of this peculiar tumor form.

In the fir t case one is truck by the pro fuse vascularity of the growth, the conspict ous clement being the large number of dilate lymph and blood-capillaries and pace The ramincation of the capillaries i ea il made out as they tand out sharply often cor taining a line of red blood cell The hyalin cords are not in this case so large or so del nitely circumscribed a will be described a Case 2 The connective tis ue element at much less conspicuou as they are so scattere among the lymph spaces and have not a this younger stage of the tumor undergon the same degree of sclerosis and hyalin change which is so much more evident i the second case as a result of the restriction of blood and lymph supply. One i in pressed however by what seems to be significant fact. In certain areas where the sections show most clearly the curling an branching of capillaries in a single plane on can see between the unbroken endothelium and the connective tix ue which makes up th tramework of the tumor small area of th hyaline which from it very relation suggest that it is a secretion product of the end the hum. Where the mixing of the materia is more marked one sees that the lumen of th paces a correspondingly restricted unt we have in some field, the mill cell inclusing referred to above. The peripheral distr button of hythine Linchese to be but a chance one i in ther field me i equally attricte by the fact that the hyaline strands are definitely included within a single line of endothe ilum and contain no cell inclusions the hyaline substance here being quite certainly a secretion within the lumen of the capillanes.

In the second case one is struck by a more characteristic appearance of the hyaline tubes. Here we have the same cellular elements as described above but in somewhat altered proportion and arrangement of these are seen definite trabeculæ of connective tissue to form a framework including capillaries of large caliber Both these factors are mark edly sclerotic. Within the enclosure of these trabeculæ is seen the much twisted and whirl like arrangement of the hyaline cords. The structure here is not essentially different from that in Case 1 but we notice a relative lack of connective tissue fibers and of capil lanes and lymph spaces seen above here the hyaline cords are larger and do not show the earlier stages of cell degeneration The distribution of hyaline too is generally one of secretion within the lumen as evidenced

by the external lining which these cords show

The interpretation to be made then from
these observations is this

That the tumors in question arise from abnormal proliferation of blood and lymph capillaries and spaces.

2 That the endothelial lining of these capillaries and spaces gives rise to a secretion of some material which gives the staining re action of connective tissue hyaline.

3 That this hyaline substance receives a chance distribution centrally or peripherally

to the secreting cells.

- 4. That the excessive proliferation of the vascular elements meeting the resistance of the immer connective tissue framework and of the increasing resistance of the hyahine material tends to assume a much twisted curling convoluted structure
- 5 That the increasing tension within these convolutions from prohieration and excessive hyalize formation causes first a shutting off of the vascular supply to the tissue and ultimate necrosts of the endothelial cells and tends also to restrict the nutrition of the connective tissue elements with resulting sclerosis and hyaline degeneration

That the tumors are not of connective tissue origin I think is proved in that they quite clearly are associated with endothelial structures and in all stages show no relation to the connective tissue elements they enclose. Any degeneration of connective-tissue stroma which may be demonstrable in these tumors, I believe to be but secondary to a primary change in the endothelium in contradistinction to the view of Evetaky (6)

That the hyaline secretion is not perithelial in origin as Lubarsch states I believe to be evidenced by the fact that these hyaline in clusions are seen to be within an endothelial boundary in the greater part of the growth.

Baumgartner following the view of Malassex thinks the cells composing the main part of this form to be epithelial. He further thinks these cells exist in conjunction with a mucoid substance. The preponderance of this latter element he explains as due to the greater vitality of the mucan over the epithe-He further explains the growth as centrifugal in its course. That the cells are epithelial he attempts to prove by the fact that they do not seem to him to have any connection with the blood vessels. He describes them as being atypical in the center but showing the characteristics of cuboidal and columnar cells at the periphery of his sections. They do not show signs of being secretory so therefore he concludes that the mucoid substance is not a secretion of these cells nor is this substance a degeneration or a vegetative development of these cells. By staining reactions he is satisfied that the mate nal is not myxomatous but true epithelial mucin in nature. In a review of 400 cases described as cylindroma he chooses 83 as true to the type. Seventy four of these are de scribed from the head, three from the sacral region. He explains the presence of mucoid tissue as an embryonic remains similar to the vitreous of the eye and cites the existence of 23 cases from the orbit to substantiate this relation The description of cylindroma like areas in teratoids lends further weight to his theory of the embryonic origin of this substance. That the epithelial relation of the cells in these tumors is not valid. I can only combat with the evidence which I have offered

Ig (Ind) m fthe t gu (Iwpow) shww g has t m tr pyx anv at the d thelial cell cords od t not the hour Inde not knobe.

M reover following the analogy of this mucord ubstance with the vitreous we must look for a cell matrix which will be the origin of this mucin just as the vitreous takes its origin in the epithchium of the posterior zone of the chlary body. That the substance is not mucin i certain in these two cases and that it is a sextition of the cells seems a logical conclusion though the secretory power of these cells cannot be proved. The underlying idea of Baumgariner and others that these tumors are possibly embryonic in origin and assume a development during extra uterine. Infe is a conception which seems quite tenable.

That the cylindroma may be described hitly is a tumor entity. I believe is justimable because of the fact that several of the cases described under this title have shown no clinical or pathological relation to either car tumomata sarcomata or enchondromata as believed to be the case by Foerster (7). R. Volkmann (8) and R. Maier (6). Y recent report by Kichard Weil (10) of a parotid tumor which he has considered as an example it cylindroma gives evidence of the frequent. It is mit taken identity of the tumor form. The

Hig Cylindroma (th tingue (high poller) sh wing the relative for nective to sue strom it the end thelial cells and hyaline tubes and the lint matter but not the bysiling to the end theliam of capillaries and lymph spaces.

clinical history of his tumor might fall well within the limits of the cylindroma, but his brief discussion of its histological nature and his photomicrograph certainly do not con form to the type of tumor I am describing as cylindroma It is undoubtedly such degenera tive forms of epitheliomata that have so complicated the exact classification of the cylindroma Cylindroma i a descriptive But the cell of the cylindroma does not partake in character or arrangement of the features of the basal cell Dr Oberlin s Case 3 from the uterus is also an example of a malignant growth with degenerative areas of the nature of cylindroma cases should I believe be called sarcoma cylindromatosum to express this resemblance to cylindroma True cylindromata show few degenerative changes in some cases mucin being demonstrable. On the contrary they seem relatively benign and evidence micros copically only the arrangement and elements described above

Fig. 3. Cylindroma of the tongue. The dense onto two-thous appole is show enclosing the tumor indiseprating it from the tongue muscle.

The exact nature and origin of the cylin droma which will lead to its final lassift a tion among tumors must remain undecided I believe however that the evidence submit ted in my saves combined with that of similar reports points to a logical conclusion In the belief that the endothelium may take part in the formation of sarcomata, the cylin droma should be considered as a variable form of sarcoma according to Borst (11) cylindroma is not clinically or microscopically of the character of sarcoma however tusue is not sarcomatous and not infiltrating but a sharply circumscribed by a connective If then we consider this form tissue cansule as essentially endotheliomatous in what does it take its origin? From the cases of true cylindroma described in the literature we are struck by the benignity of the form clinical history usually is that of a slow growing nodule lasting over a period of years. The one history which I submit may seem to indicate an exception to this statement. We cannot be certain however that the history of more rapid growth in the last three months is not due in the case to some degree of inflammatory infiltration due to the mechanical irritation of the tumor proper. Considering then the long history the benignity and the simplicity of the tumor-element a connective ti sue hyaline in a base of capillaries it seem logical from pathological experience to consider this of the nature of angioma simplex or perhaps hypertrophicum. In this event cylin froma may be described as of embryological origin of a type of angioma assuming its clinical characters usually some time in adult life. The hyaline may be be lieved in this case to represent some sort of an attempt on the part of the body at a reparative process in the existing angloma

Further evidence a to the luration of growth location clinical manifestations and microscopical characters in young forms alone can give thi tumor it definite place in the classification of tumors. Until then it may quite logically be considered under the title of cylindroma endothelioma cylin dromatosum or angiona. Vindromatosum

I desire to express my gratitude to Drs Warthin and Weller for valuable assistance and advice in making this report.

DEPARTMENT OF TECHNIQUE

FLUOROSCOPIC ROENTGEN INJLCTION OF THE BLADDER

R I H SKINNER M.D. K. A CITA MI S. RI

ROUNTG INOGRAMS at the Halder filled with pagine condition and recovering the best frequently reported such roenigen examination are ligreat value in testal for return to the intravesticular turn renlarged reports.

There are crain advantues to these rentgen examination in the paque innext in are made under the response control. It is extremely implied in the patient to be upon the horizontal roomtientally with the horizontal roomtientally with the horizontal roomtientally with the horizontal roomtientally with the horizontal roomtientally with a horizontal roomtientally with a horizontal room to

by the gravity method

The gradual enlargement of the opaque bladder had will witnessed flut rose pically the patient being turned from me ide to the other in order to nite the lisati in of diverticula upon the postering ranter in bladder will. The transverse bladder had witnessed also and it especially valuable in dilatation of the bladder anter it vand upward in cases, u piciou, of a patient unach.

In the case herewith reported No 6345 Mr ON reterred by Dr. Den low the provisional ex toos pix diagnosis was a diserticulum near the position 1 the left ureteral onnie which could not be entered with the existoscope for

vi ual exploration

The patient lay upon the fluor recopic contgentable with the knees slightly fleved over a pillow. The catheter was inserted to the bladder and a large vrings filled with barium emulsions was attached; the catheter. The fluoroscopic screen wa placed over the bladder area anterior) and the rentigen tube tocued undermeath this area.

A the emulion was gently forced into the ladder by the vringe the opaque shadow grew apace. After 16 unces of opaque emulsion had been injected no diverticulum having been observed upon the lateral bladder wall, the patient was rotated to the right and left sides and still in diverticular shadow presented itself. Newmig the patient laterally, no noticed the

projection tithe Hall cranteriorly and all veithe symphy is public with a created cutting to the bladder wall, but no hyericulum, was apparent

When the patient was returned to the riginal position upon his back, we not redailing paque shadow extending upon and trom the left uperton of the left ureter. Find broad had we extended all we the pelvic utiling to ward the left kidney (Fig. 1).

R entgen negatives were then taken in several positions and the long halow interpreted a a dilated left ureter. The pennig, in the Hadder wall which was thought to be the mouth of a diverticulum was no doubt the chlarged ornice at the dilated left ureter.

Fig. Show ling op que shed toding up rd from left perior pitt so slibkadder had win th usual position of the litt...ter

This method of fluoroscopic injection of the bladder is valuable in suspected diverticulous because so frequently the oil retricula ar behind the full highler shadow and the best posture is re-

rad ograi hy an be secured with the fluoroscope thus avoiding unnecessary delay or repetition of the lindder injection as when radiography alone is practifed.

The accompanying pictures Figs 1 and 2 how the state of the scretum of the patient soon after he wa admitted to the Ur Dgical Service of the Philippine General Hispital Surgical Department A 1 seen in these pictures the enlargement of the scretum is so remarkable that it almost t uches the inner and upper part of the knee joint. The vein are a beautifully distended that they con titute a net work early seen with the naked eye. The enlarged scrotum is distinctly fluctuating. The right groin is flat although a little bit more elevated than the left In the inner aspect of the sere turn and upper part of the same just below the gland peni a mail bulging is noticed which correspond, to the left testis. The right groin is also fluctuating although the fluctuation is not so diffict a that of the scrotum. Before the operation a diagnosis of hydrocele of the right testi with possible hydrocele of the cord had been made An operation was advised and agreed upon

On performing the operation, the writer was surprised to encounter condition, beyond expectation as are expressed in the post-operative

diagnosis

A BLADDER SUTURE

B ALEXANDER HAMILTON PEACOCK M.D. SKATTLE WASHINGTON

ALL who have attempted surgers upon the bladder have had more or less difficulty in cloung the viscus, either watertight

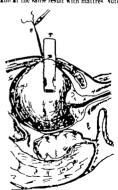

or around a drainage tube The causes of this difficulty are () the distance t lies from the permary increaon (skin), the bladder lying oute low in the pel 1s especially in men who have a thick abdominal wall (2) the fact that in all but cases of a hypertrophied and dilated racus the bladder cannot be brought up to the initial wound as other pelvic organ can he (2) that the bladder is a contractile ocean and apparently shrinks into the size of a golf ball and (a) that after the bladder has once been in cited the incision is ant to develop into an uncontrollable tear due t the insertion of the speculæ instruments, or the ingers of the operator and some bladders tear very erry easily All these things contribute to making a closure of the bladder at times, slow tedious and embar ra ssine

Incher rathere. The most popular auture has been the pre-incusion anchor autures one on either acid of the median line. They have been a great help serving chiefly as tractors and eletors of the edges of the bladder wound. How ever they frequently tear themsel es loose and are of doubtful aid in the final closure of the

Fig. 1 Permeal 6-b-book needle dotted and dashed hise crenelated puric-string suture

bladder To ercome these disadvantages the foll wing suture has proved most satisfactors as it easy to insert easy to the and gives a perfectly tight wall

Modified purse tring bladder suture. A peripent fish book needle is used as pictured in Fig. 1. \ Chromic catgut size No 2 twenty-day absorption is the best suture material After exposing the bladder retractors are inserted and the peritoneum pushed and rolled back off the upper nde of the vycu No matter whether large or small full or empty the dome of the bladder at ways shows itself. This i grasped at two points in the median line with toothed forcers. a purse string suture is started at the fundus down the right side then turned and run up the It will be noticed that the stitch has a crenelated appearance as ea h new bite into the bladder wall fall into a different line the object being t avoid bringing all the strain and pull on muscle tibers of the same I ne and group. We sum at the same result with mattres, sutures.

1 ig -5 Suture tied round drainage tobe T drainage tube B bladder all dra tight against drainage tube

The bladder is now ready to puncture. After completing the intravesicle work a drainage tube can be inserted or a retention catheter placed in the urethra and the suture drawn tight. A reinforcing suture can be used, but is quite un necessary as the natural contraction of the muscles of the bladder wall further assist our purse string. A small cigarette drain can be used in the space of Retzius. This suture has been employed for simple drainage, exploration resections for papilloma and prostatectomy all with uniform success and stringture.

I can recommend its use for the i llowing

r. It is easy to insert

2 It stays in place and does not tear the blad der

3 It lessens bleeding from the large veins in the bladder wall

use bindder wall

4. It saves much time in clasing up the blad

der
5 It makes a tight libure of the blaller
possible insuring a drier wound an libetter
drainage

PITUITRIN IN POST-ABORTION CURETTEMENT

By HENRY DAWSON FURNISS MID FACS NEW YORK

FOR the past year it has been my practice to give one cubic centimeter of pituitary extract hypodermatically before curetting for incomplete abortion

The advantages in doing this are that it produces firm uterine contraction which makes the procedure almost bloodless and much more easily done. Because of this contraction the uterine cavity is small and the contracted walls present a resistance to the curette which makes their cleansing less difficult and, I believe, lessens the risk of uterine perforation.

The most favorable time to give the pituitrin is 15 minutes before the actual curettement is

begun. When the interval between the injection and curettement is less the resulting contraction has not been so pronounced and the result not so good. As yet I have not had any post operative bleeding following the use of the pitutin but realizing that such a possibility exists it is advisable to pack the uterus and vagina with hodoform gauze which is removed at the end of 24 hours. Should bleeding sour and be troublesome ergotole can be given hypoder matically.

With the use of pituitrin the blood loss 1 so much less and the curettement so much easier than without that I strongly advocate its general use

DR. F. E. PIERCE read paper ent (led Tra ma t the Back and Spine (See p 133)

DISCUSSION

Dr. DANTEL N. EREKOBATH. This is an exceedingly valuable paper t everyone of us aspecially those who hold important mairoad positions. We are indebted to D. Plerce for bringing to us his carefully edited list of cases. I believe that we over it to these pettents, both from the standpoint of a defendant corporation and that of patient not a claimant for inquiries, to be exceeding 5th through in our examination and not regard the patient as mailingeren. We are very spit to examine them be rriedly and pass them along as cases of sprained muscles, etc.

I have had occasion in the last two years to see number of cases which were diagnosed as min injuries, and yet the persistence of the symptoms caused me to mak most thorough examins! n. I wish to speak in this connection of fractures of the transverse processes of the lumbar vertebre as being frequently overlooked, because w think that such things could hardly be possible from an injury of the back. A roentgenogram ought to be mad of every no f these cases not only in the region complained of but if the entire spine, not nly in an anteroposterior direction, b t if possible in a lateral direction. Some of the cases if fracture of the ribs near the vertebral column are ant to be overlooked. and again there are cases of fractures of the hith humbar vertebra, crushing fract res, without any othe symptoms than those of pai There may be no symptoms on part of the spinal cord, hence it is almost impossible to diagnose them without good roentgenogram.

Finally I would speak of a superficial method we han of examining some of these cases which of the hist ries reminded m of and that is injuries of the urnary tract. I had occasion bout two years ago t see a patient who had sustained an injury of the kind D. Pierce described, from lifting a heavy weight. The patient was from Grand R pids, Michigan, and had passed from ne prac titio er t the other with a history of repeated colics. The colics ere referred to one side and niv by going into the history thoroughly did we find the colic started on one sid of the back and radiated down the same as a typical ureteral c l c. W made use of a method of diarnosis that I can warmly recommend t you and that is to mak a pyelogram and in this case a found a stricture of the reter an inch and a half below the pelvis of the kidney as the cause of this man's symptoms. Thinking there could be no connection between the injury of the back sustained by flexion or over extend of th back and injury of the preter, we later proved by a pyelogram at peration that there was hydronephrous secondary to the infury of the So I ould make an urgent plea for a more thorough examination in these cases, tilizing every method before passing them along as sorains or possible cases of malingering

Dg Fra k E Pirrez (closing) I ha nothing further of importance t add. I purposely omitted fractures because it is such large field.

The importance of making careful examination in these cases as emphasized by Dr. Elsendrath cannot be urged too trongly I have had a number of cases in which the diagnosis was mad of sprain where the X-ray has shown — fracture of an entreman of trainsverse process, or a fracture of an articular process which had caused pressure on the spinion and increase and ymporism which our examination could not bring out except through an examination of the country place. In easier cought to take a superficial going it do justlee to the patient we aboud to be about each of the country of the coun

Dr. Whilam Hearrer read a paper entitled Emploitis Following Hermotomy (See p. 07)

BOOK REVIEWS

A CRITIQUE OF NEW BOOKS IN SURGERY

BY MAJOR C SEPLIG MD S AT L I

O \ E of the best book reviews I have ever read wirtten by Wider Lippman) did not even so much as mention any specific book by title. The reviewer suavely granted himself the hierase to select a volume only to consign it to oblivion by leaving it nameless then he proceeded to use it as a text from which to preach a serion on the meaningless mumble jumble of much of our present day politice-sociological literature. And after all whi it is not legitimate to do Just this very thing? Why not now and then regard a book as the expression of a tendency rath r than as a concrete product to be measured and trimined by the ordinary conventional standards?

At all events this is the spurit that moves me after reading two new volumes by Crile these volumes are toun led on the same material that has served as the basis for other books by Crile already reviewed in this department. In these earlier review we have expressed rather emphatic dissent both from Unles philosophy and from his Of ourse this is after all only a matter of judgment and someone has said wisely regarding iu lement Tis with our judgment as our watches none goes just alike, vet each believes his own If Dr Crile himself should take exception to our estimate of his philosophy and logic he surely can not cavil at our unqualitied admiration of the tend ency mirrored in these two latest and the two or

thre earlier volumes dealing with anoci association.

But before stating this tendency it would not be amiss to furnish a few lescriptive words regarding the two volumes. The Americ Dette a short monograph of seventy pages a reprint of th Wesley VI Carpenter lecture published a few months ago in the Jou nal of the American Med scal Issociation. The main thesis is Cole a now well known doctrine that the body is a mass of put nital energy and that the potential energy is converted into kinetic energy by various stimuli calling forth adaptive responses Uter detailing this so-called kineti mechanism Crile dilates upon the function of the adrenals and thyroids and then, under separat hapter heads considers the control of the kinetic drive kinetic diseases (Graves disc se car hova cular disease. Bright a disease and diab test and surpleal in thods of controlling The kins is by: 1 Philippoper and Con roll By George V.

th kineti len it finally a ummar. Minan Idaplies Me ha in a time per former of three hundred edd pages 1 (5d) a spatial tonof the loctrine that man it being the last fight is as do other me has min. A very still the introduction ontaining it if Nerral garantities open to question if filowed by a higher revocation man salight in it in the remain. The follows for the first firs

More specific or d tail 1 tat ment is not called for since our aim is merely to paint ut in gin ral what books of this sort m n And the encin just this that the man who writes them i thinking briskly along lines somewhat his rient from the current of his main lite work. One would like to call them avocative books. They tea hour the service of an avocation Legit mat x eption might be taken to our haracterisation of su h effort as an avocation but certainly no worked ty oper ating room or urm il lib ratory turns out su h product. If for the sake of argue ont we were forced to admit that these two book are listinctly surgical and represent ultimat ly the opinion of a surgeon on surgical disease w hould say Then let us have a few mor just su h volum s These are days when men have to be for ed to think and imagine and Crile (urn) hes the most impelling stimulus to this end Finally ev n if I be on strained to view the books a pure surgery I shall counter with the statement that they represent the artistry of surgery as contrasted with the artisanry of the usual book de oted to the more specifically technical subjects of surg ry proper

HERF is a book that speaks for itself and requires no comment from the reviewer regarding the tendency that it manifests. One my by par loned for entertaining the suspicion that e-cryfning ev-ry where is tending toward war. Thi much I kn we that within the year I have had to rearrange my shelves several times in o ler to make room for new war surgery volumes.

Hull's book 1 pra tically along the same lines and after the same fushion as the volume by the mann on II. Alteriji II. R. R. () is prefer by Sur Mari K. Wab VI. Path belok Bith on which is prefer by Sur Mari K. Wab VI. Path belok Bith on which

Frenchman Delorme the English work by Makins the various contributors to the Oxford War Primers, and th treatise by the American La Garde. The difference lies in the fact that this, being the latest volum t appear presents the latest conclusions reached by the Eorithis nurrecons

For example the first chapter on The Bacteriology

of Wounds in War summarizes very clearly Sir A. E. Wright a at dies wound infections and their treatment and Chapter II on The General Condition of th. Wounded summarizes admirably the data of the various offecting and base hoststals. Chapter III on Th. Treatment of Wounds and Chanter the Treatment of Wounds by Saline Solutions furnish about the only dat that may be appropriated advant geously by the civil surgeon in his routine work. The remaining eleven hapters deal with surgery from the regional point of ew and although of unusual interest hardly call f detailed comment, save to mention the salsent f ct that chest wounds are still bandled along lines of th strictest conservatism in contrast with wounds of the abdomen which are being treated more and more radically (as regards early operation o ex ploration) in accordance with the rules that have been followed in civil practice

There are several contributors to the little volume and they have d ne their work well. The book is built for the knamack, and is built admirably for

this purpose indeed

A RECORD of accomplished purpose a not easily incorporated in review of this latest product of Mr. Lane or better this joint productio of M Lane Mr MacMah n, and Mr James, for the latter two sentlemen contribute chapters on Speech Traini g and Dental Treatment of Cleft Palate respectively Judging from the title the book is osteraibly devoted to a considerate of the subjects Cl ft Palat and Hare Lip. As a matter of fact the latter is quit ignored save for a table showing the frequent coexistence of the two conditions, which table in itself sufficiently warrants more than merely asual reference. After a lengthy introd cti n, M Lan reveals his purpose by emphasizing the two pol t which really represent the sum and substance of the entire book. The first is that cleft palate operations are to be done very early and the second is that his method of operating by fashloning mucopenosteal flans is preferable to the simpler one of paring co-apting the margins of the cleft.

In the high of illuminating experienc surgeons very generally inclin to accept the latter dictum as correct and concede t. M. Lane well deserved credit for originating and popularizing so valuable an operation. They may well concert also in the first pot to the extent of divising operatin before dentition interferes with the reflection of adequate mucoperioates flaps, and before the child acquires permanent speech defects as speech devel ps. B. t.

it is possible that Mr. Lane presumes a bit in recommending operation opon the day of birth, or as soon thereafter as possible in the basis that the newly born child is always bealthy (p. 3.) It is well recognized that serious consequences may follow even the mich simpler droumcision operation upon even slightly jaundiced bables

A SHORT pan of less than two decades has sufficed t place the problems of i ternal secretion into the very center of medical interest and t incite count less number of students to devot their energies to this fascinating subject Virchow's cellular pathology once supreme and all-embracing no longer seems t stand on its former firm foundation and the camp of those who endeavor to establish th old humoral pathology a new and acientific basis is dally growing is ger. That chin unconditional defectio is to say th least premature at the present day will hardly be denied by the majority of medical workers. Yet, the countil ted mass f clinical and experimental evidence is so immense. and nly e ceeded by the number of more or less plausibl theories that it has been extremely de strabl to possess critical mmary of our present knowledg of the nat re nd significance of the glands with I t mal secreti n. Out I this need was born Bledi mo mental work on the experimental physiology and pathology of the d ctless glands Thu was foll wed by an equally important treatise by Falt which first ppeared in German in 9 3 and ow appears in English translati n.

Falt has set himself the task to consider the chinical aspects of the diseases I the ductless glamis, and his deductions and conclusions are based pon an exhaustive study of the literature and n exceptionally large number of personal ob-servations. The opening chapter is devoted to a general considerati f the n rmal ad pathological physi logy of the ductless glands, their reciprocal action their i terrelations t other organs and their aff ence pon th constitution of th entire organism There follow nine chapters dealing separately with the diseases of the thyroid gland, cretinism, affections of the parathyro da thymus hypophysis nd epiphysis lesions of the suprarenal apparatus, the status lymphaticus and hypoplasticus, and finally diseases of the sexual glands. The last named chapter comprises consideration of the interstitial glands and discussion of changes i the generative apparatus. This includes malformations, hypogenitalism (cu ucholdum) hypergenitalism chlorous, and osteomalacia. A shirt chapter is devoted to pluriglandular diseases. Infantilism, dwarfism, rachitis chondrodystrophy and mongol ism are united in a chapter on vegetative disturbances that d not depend directly on diseases I the d ctless glands. In a other chapter the diseases of the insular apparatus of the paperess and their

Cleft Palete and Hare Lap By Set Arbeitheet Lane Bart. V. F.R.C.S. piled London, Adherd & Sen. 6.

r lation to diabetes are treated and the final chapter deals with the different forms of obesity and adu positas delerosa

A comprehensive list of bibliographic references at the end of the book covering no less than 60 pages will prove of great advantage to anyone

who wishes to study special subjects.

As can be seen from this brief survey of the table of contents, the field of study is enormously large and Falta has endeavored to bring order into the existing chaos. His guiding principle has been this that the diseases of the ductless glands altogether are due to quantitative alterations of the respective internal secretions, that is to say either an increase or a diminution of function Such a classification which I aves qualitative disturbances of secretions or percented functions of the clands entirely out of consideration is bound to create objections. Falta himself anticipates su h opposition but he meets it by contending that the physiological chemistry of th internal secretions is still in its infancy author has endeavored to attack the difficult and omplicated problem with strict objectivity in a held where our actual knowledge is still in complete in spite of the imposing material collected there is a great temptation for theories for which the convincing experimental and chinical proofs are still la king

In medicine everything is in motion more so in this most modern bran h of pathology than in ther fields balta s book is not the last work it is only a milestone in the development of th tudy of the internal secretions. The pathology of th hypophysis and the sexual glands for instance is only in its initial stage. The question of diabetes is still sib jud ce an I the val has hardly been drawn from the obscurity of the nature of the plunglandular Justines

Let the value of the book cannot be overestimat d. The astounding erudition industry and ingenuity of the author fill the reader with sincere respect. The work represents a permanent acquisition for medical literature for it will a t as an inspiring and tructifying timulus upon other schol

r to study the clinical aspects of the diseases of the du tless gland

To have translated the work and to have but it within reach of English peaking student laborious undertaking of grat m rit th Jubli her too desert their har flappreciation. The translator has still further increased the value t the book by collecting rec nt Am ri an in l Engli h views in an add indum at the end of nerty very chapter

This is the second I ngli h lition and it seem more than likely both from the far reaching importance of the ubject and the intrins in the of the book that a third dition will sond need Un der these circumstan is the rivid in annot r frain from expresing a friendly intrusm as to the phraseology of the trin lation. Typograf hi al errors and misspelled nam of foreign auth is will of course cally be printed. The Linglish titl sounds ankward District ot th Ducties would seem pr 1 rabl More important Gland to my mind is the all too faithful rendering of the German text. It seems unn wasary that the fact of its being a translation should be made so painfully obvious through an almost photographic production of the involved (erman senten es and the genius ling & is offen led if for instan the Ger man Krankheitsbild appears bet re u as a lisease Differentiation is surely superior to picture delimitation a lit ral translati n i Ibeiae i une Leberlaenge should be expire rather than upper length. A connection between two phenom na may be not clar or obscur but not un clear and it requires a thorough kn wledge of the German language to discover that understandings merely in an gros, mise n eption However su'h d'fects ar not in urable and it may yet be in the power of the translator to make Falta a book an English classi

THL CLINICAL CONGRESS OF SURGEONS IN PHILADELPHIA

It is quite apparent at this time that the limit of attendance for the Philadelphia meeting will be reached some weeks in advance of the date of the meeting so that those surgeons who wish to attend the meeting but who have not sent in their registrations are urged to make application immediately to the Secretary General Dr. Franklin H. Martin 30 N. Mi higan (ve. Chicago Illinos). When the required number of registrations has been received no further applications can be accepted.

A careful survey of the operating amphitheatter lecture rooms and laboratories of the several medical schools and hospitals in Philadelphia a to their capacity for accommodating viring surgeons has been made and the limit of itten linic based upon this survey. The levi u a it of these clinical meetings has become to great that the plan of limiting the attendance and requiring advance registration was decided up in to prevent overcrowding. This plan assures accommodations at the clinics for all who hold membership cards and has worked satis-

factorily at the two previous meetings in London in 1914 and in Boston in 191

MEMBERSHIP-REGISTRATION FEF

The Constitution of the Congress provides that all subscribers to the official journal. Sur General Ge

THE CLINICAL PROGRAM

The schedule of clinics and demonstrations to be given by the clinicians of Philadelphia during the week of October 3d as published in these

pages is a tentative one and is to be amplified and corrected so that the final program will properly represent the clinical work of the Philadelphia surgeons. The Committee on Arrangements has planned for a complete showing of Philadelphia s clinical facilities in every department of surgery including gynecology obstetrica genito-unnary surgery orthopedics, surgery of the eye car nose, and throat together with many demonstra tions on horderline subjects.

HEADOUARTERS

Hendmarters will be established at the Bellevue-Stratford where the Ball Room Clover Room Red Room, Green Room and adjacent foyers and smaller rooms have been reserved for the use of the Congress. These rooms are located on the second floor of the hotel and provide ample space for registration rooms and ticket bureau bulletin boards, etc. the Ball Room being used for the evening meetings.

Headquarters will be open on the afternoon of Saturday October 21st and on Sunday the 22d, for the registration of members. The program

of clinics and demonstrations for Monday will be bulletined on Saturday afternoon and on each afternoon beginning on Monday the complete program for the next day a clinics will be posted on bulletin boards in headquarters. A printed program will be issued each morning and special tickets for all clinics and demonstrations will be issued to members at 8 a.m. each day

SPECIAL PICELTS

The use of special tickets at previous sessions has fully demonstrated the efficacy of this method of providing for the distribution of members among the various clinica. To prevent over crowding t ckets for any clinic or demonstration are ilm ted a number to the actual capacity of the room in which the clini or demonstration is to be given. These special tickets will be issued at 8 o clock each morning for the clinics and demonstrations to be held that day a complete chinical schedule having been posted on the bulletin board on the afternoon of the preceding day and a printed schedule of the clinics dutributed early each morning

PRELIMINARY PROGRAM OF EVENING SESSIONS

CENTRAL SURGICAL DIVISION-In the Ball Room of the Bellevue Stratford at p.m.

Presidential Meeting M nday O t her

Address of Wellome ROBERT G. LECONTE. M.D. Philadelphia, Chairman of Committee in Arrangements Charles H. Mano, M.D. Rochester, Minn., Address of retiring president

Inauguration of President FRED BATES LUND M.D. Boston, and Vice Presidents JA PER HALPENNY M.D. Winnipeg, and S. M. D. CLARZ, M.D. New Orleans

Presidential address b FRED BATES LTND M.D. Boston. The Indications of Ch. lengtectom. J. M. T. Finner, M.D. Bultimore. Drainage of the Gall Bladder.

Charles H. Mano. M.D. Rochester Minn. Cholecystostomy vs. Cholecys ectomy.

Discussion. J. C. Dacosta, M.D. and John B. Draver, M.D. Philadelphia.

Tu s'av Odeber 4

DEAN LEWIS M.D. Chicago Fat and Fascia Transplantation.

Discussion Frances T. Stewart, M.D. Philadelphia.

J BENTLEY SQUIER MD New York City Lidney Surgery

WILLIAM F BRAASCH M.D. Rochester Minn. Recent Method in Kidney Diagnosi,

BRANSFORD LEWIS M D St Louis Diagnosis of Ureter Diseases with Their Surgery

J T (ERAGHT) M D Baltimore Diseases of the Bladder

EDWIN BEFR M.D. New York City The Treatment of Renign Vesical Papillomata. Including Endoves: al and Operative Methods

Discussion EDWARD MARTIN M.D. Philadelphia.

SURGERY GYNECOLOGY AND OBSTETRICS

Il ednesday October 25

THOMAS S. CULLER M.B. Baltimore Methods of Draining Where Pelvic Infections Exist J WHITERDOR WILLIAM M.D Baltimore Steeloods of Draining Where Peivic in
Discussion E. E. MONTGOMERY M.D Philadelphia.

J WHITERDOR WILLIAM M.D Baltimore The Abuse of Casarean Section.
Discussion Edward P Davis M.D Philadelphia.

10

GEORGE G WARD JR. M D New York City Treatment of Inaccessible Vesico-varinal Finale Discussion JOHN G CLARK, M.D. Philadelphia.

C. IETT MILLER, M.D. New Orleans Surpeal Treatment of Puerperal Pyremia

Discussion Barroy C. Hrest M D Philadelphia.

THOMAS J WATKINS, M.D., Chiengo Cystocele and Prolapse Discussion BROOKE M. AMERICA M.D. Philadelphia.

Thursday Oxfober 20

C A. PORTER, M.D. Boston Surgery of the Peripheral Nerves Discussion Charles H. Frazier, M.D. Philadelphia, and John H. Gibbon M.D. Philadelphia. WILLY MEYER, M.D. New York City Cancer of the Breast

WILLIAM I MAYO, M.D. Rochester Minn Cancer of th. Stomach Discussion FREDERICK W PARHAM, M.D. New Orleans.

GEORGE E. ARMSTRONG, M.D. Montreal, Canada. Cancer of the Large B. well Discussion STUART McGuirr M.D. Richmond and E. Wyllys Andrews M.D. Chicaro HOWARD A. KELLY M.D. Baltimore Treatment of Cancer by Radrum.

JAMES T CASE, M.D. Battle Creek, Mich. Treatment of Cancer by \ ray. Discussion. George E Prantez, M.D. Philadelphia.

DIVISION OF SURGICAL SPECIALTIES- At the Bellevue Stratford at 8 n.m.

Tuesde October s

Sympodum on Ophthalmic Surgery

ARNOLD KNAPP M.D. New York City The Present St tus of Extractio f Cataract i the Capsule. WALTER R. PARRER, M.D. Detroit Corneoscleral Trephining Usually Known as the Elliot Oncration.

Wednesday October 5

Symposium on Rhinological and Laryngological Surgery

CHEVALIER JACKSON M.D. Pittsburgh Some New Developments in Bronchoscopy

R. CLYDE LYNCH M D. New Orleans. The Technique of Suspension in Bronchoscopy and Caopha goscopy

HARRIS P. MORIEZE, M.D. Boston. The Webs and Pouches of the Upper End of the Geophagus. Discussion D Braden Kyle M D George M Coates, M D Curtis C Ever M D Phile delphia

Public Meeting Friday October 7 in Witherspoon Hall, at 8 p.m.

Under combined auspices of the Philadelphia County Medical Society the Department of P blic Health and Charities, and the Clinical Congress of Surgeons of North America. WESTON A. PRICE, M.D. Cleveland Care of the Teeth. (Illustrated by lantern and cinematograph.) JOSEPH C. Bloodgood, M.D. Baltimore. Diagnosis of Cancer

ROBERT W LOVETT M.D. Boston Description and Illustration of Curable Deformities and the Importance f Their Proper Treatment.

EDITORIAL ANNOUNCEMENT

The Editorial Board of the International Abstract or Surgers has desired for some time to present a comprehensive review of the work done on surgery of the eye. In this branch of scientific indexvor there is work being accomplished which is of the utmost value to the patient which has reached the height of technical proficiency and which is virtually unknown except throughout the relatively small group of men devoting their efforts to thus so-called minor menalty.

Perhaps at this time no subject is of greater interest to the ophthalmic surgeon than that of glaucoma, the literature concerning which has become at once extensive and valuable. In this maze of competition the interested reader finds a wide divergence of opinion. Partly to clarify this confusing situation and in part to give ophthalmic surgeons a broader scope in our columns we have secured a collective review on the surgery of glaucoma from the pen of Dr. Emory Hill of Chicago. While a discussion of this subject at the present time may lack finality. Dr. Hill s experience as a turbent and surgeon has enabled him to present the matter broadly and with such decision as may safely be arrived at today.

Other collective reviews to be published during the next few months are

INTERNATIONAL ABSTRACT OF SURGERY

SEPTEMBER 1916

COLLECTIVE REVIEW

CONGENITAL MALFORMATIONS OF THE NECK

B) (EORGE DE TARNOWSKY M D. F.A.C.S. CHICAM A tending Surgeon Cool, County and Ric commond Hospitalis

IIISTORIC

ACCORDING to V A Funk (8) Ascheron in 1832 must be given the credit of first discovering that congenital cysts and sinuses of the neck had a def inite connection with aberrations of fortal branchial elefts Somewhat later Roser and Koenig reinvestigated the same subject and confirmed Ascheron's undings Lilienthal (11) and DaCosta (22) credit Mayer in 1833 with the first comprehensive report on carotid body tumors although Luschka in 1862 so popularized the ubject that this body is now very generally known as Luschka's gland After a most careful purusal of the literature, the reviewer has failed to find the original authors who first classified cystic hygromas lymphatic cysts hæmorrhagic cysts or teratomata of the neck among tumors of congenital origin Exact knowledge of these malformations appears to have been acquired through a slow process of medical evolution Giacomo (32) believes that Wegner should be given credit for describing cystic hygromata of the neck in 1827

FREQUENCE

Burke (i) makes the statement that thyroglossal cysts occur with comparative frequency Dowd (51) in looking over the records of the New York Surgical Society found no report of a complete branchiogenic fistula thus indicating it comparative mrits. The records of the Cook County Hospital of Chicago from 1900 to 1916 County Hospital of Chicago from 1900 to 1916 reveal 5 cases classified under the heading of congenital malformations of the neck. A careful analysis of these 8 cases compelled the reviewer to reject 6 of them, the clinical history operative findings and lack of pathological report all speaking against their embryologic derivation. One case a doubtful branchial cyst was a fluctuating circumscribed welling the size of an almond lying subcutaneously over the center of the right sternomastoid muscle operation the tumor was found within the sheath of the muscle but there is no mention of any obliterated duct proximal or distal to the tumor and no pathologic report is attached to the case The eighth case was an undoubted thyroglossal cyst McKenty (1) reviewing the records of the Royal Victoria Hospital for ten years (1904 to 1914) was more fortunate being able to tabulate 15 branchiogenic cysts 5 branchi ogenic carcinomata, o thyroglossal cysts and i carotid body tumor-a total of 30 cases. Collison and Mackenty (a) were able to collect to cases of carotid body tumors in the literature up to 1913 Of these 60 cases 4 had merely been accidentally found at autopsy and 2 had been examined post mortem the nature of the growth not having been recognized ante mortem Dowd up to 1913 collected reports on or cases of cystic hygroma of the neck and only 35 cases involving the availa or pectoral regions

From a careful analysis of cases reported to date it becomes self-evident that in general the diagnosis of congenital malformation was only arrived at after the operation. In the case of congenital crysts only a microscopic examination of the epithelial or endothelial lining of the cryst.

wall will reveal the true nature of the tumor Clinically a definite diagnosis of congenital fatula can only be made when it is either complete the extending from the pharyngeal wall or foramen occum to the lateral or anterior surface of the neck or of the incomplete metrial or incomplete external types the opening either on the aufface of the neck or in some portion of the pharyna. A pre-operative differential diagnosis between a true branchial or thyroglosial cyst (closed at both ends) and a hygroma cysticum coll, would appear to be impossible.

CLASSIFICATION

The classification of embryologic malformation has never been placed on a firm basis. Each author has apparently been content to work out his own scheme, with little or no regard to previous publications Thus O C Smith (6) in his otherwise aniended classif cation of tumors of the neck, includes angromata hypromata and dermoids of the neck under neoplasms and not among embryologic malformations. Murphy (2) classes the above under the proper bending but includes carotid body tumors among mallenant diseases of the neck. He also classes hypromata as bursal cysts. Smith classifies carotid body tumors under the heading tumors of special organs" Branchiogenic cysts are classified by the same author under two heads (1) congenital (2) malignant, which is needlessly confusing Kirmisson (14) divides all congenital cysts of the neck into (1) serous (2) dermond (3) muc id His serous cysts are evidently hygromata, for he describes them as large multilobulated extending from the lower law to the clavicle and from the median line almost to the spinous processes of the vertebrae. There may be as many as 100 pockets in one tumor These tumors have a tendency to penetrate muscles (pseudomalignant) they may even pass under the clavicle and form axillary cysts, or under the manubrum to the enterior mediastinum. He considers the etiology of serous cysts under two beadings (1) venous, because of their frequent intimate connection with the interior jugular vein and the chinical fact that the contents of the cyst is frequently bloody (2) lymphatic, because of the dilatation of surrounding lymph channels. Dowd (10) writing on the subject of cystic hypromata of the neck, states that three types of growths have been included in some of the descriptions (in medical literature) (1) cystic tumors which have endothelial linings and which grow with much power through the tissues of the neck or downward under the claylele into the axilla or pectoral region (2) lymphangiomata and (3) brunchial cysts. He correctly maintains that only those of the first type should be called hymphanas.

The following cla infication based on embry ologic microscopic, and clinical data, has been compiled from the case reports to date

i Branchiogenic

- (a) Complete fistula (branchial fistula of Roser) patent both ends
- (b) Incomplete fistula | Internal (Cvstic fistula) | External
- (Cystic fistula) \ External (c) Branchial cyst closed both ends open
- in intermediate portion
 Thyroglossal
 - (a) Complete fistula (extremely rare)
 - (b) Incomplete internal (rare)
 - (c) Incomplete external (rare) (d) Thyroglossal cyst (usual type)
- 3 Aberrant thyroid gland.
- Supernumerary thyroid
 Lymphangioma symplex and
- cavernosum)
- 6 Hæmorrhagic cysts (bemangioma congenitum)
- 7 Hygroma (hygroma cysticum colli congeni tum)
- 8 Dermoid cysts (in parotid gland near floor of mouth in thyrohyoid or submaxillary region) Kirmlision (14)

o Carotid body tumors (b) Secondary mails

, IMII

EMBRYOLOGY

Branchiogenic fistula or cyst. In the development of the anterior part of the digestitract there are formed bilaterally symmetrical lateral diverticula which pressing aside the lateral mesoderm of the head, come into apposi tion with corresponding invarinations of the The endodermal diverticula are termed pharyngeal pouches, while the ectodermal in aginations are known simply as branchial grooves. By pressing aside the mesoderm the ectoderm and the endoderm for a time come in contact and fuse forming the epithelial closing membrane which breaks through in all forms that have a branchial resouration. The branchial grooves and pharyngeal pouches thus become continuous and together form the branchial clefts. Under normal conditions this fusion and breaking through does not occur in mammals. Between the branchul clefts are the branchial or visceral arches, each of which contains a skeletal red the cartillaginous branchial arch, its muscula

ture an aortic arch and a nerve trunk. The branchial arches are named in succession the mandibular hvoid and branchial arches proper. The first branchial cleft is also known as the hyomandibular cleft (Keibel and Mall 57).

In a four week-old human feetus there are four branchial clefts which correspond to the gills in the tish. All these clefts should become completely obliterated or in other words, the arches or bars separating the clefts should coalesce (with the exception of the first cleft which forms practically speaking the canals opening into the pharynxi leaving the neck perfectly smooth The auditory canal develops at the site of the first cleft (52 53) The eustachian tube the middle ear and the external auditory meatus would really form a complete fistula but for the membrana tympani which represents the thinnest portion of the cleft and contains two lavers of epithchum one from the ectoderm and one from the endoderm. This near histula is really very umlar to the real fistulæ which sometimes exist in the neck at the site of the second cleft. When maldevelopment of the first cleft occurs at is ant how itself by tabs in front of the ear or defects of the enrit wilf and occasionally is a sociated with detective termation of the mouth (Dowd 10) If nature tails in any of these particulars, there is produced a congenital fistula a cyst or both Funk 51

The region that corresponds to the outer open ing of the second branchial cleft is to be found at the antenor border of the sternomastoid muscle The second pharyngeal pouch corresponds to the tensillar depression the openings of the third branchial cleft (pharvingobranchialis) are to be laked for near the larvnx A fistula of the second branchial cleft must lie if the development t the vessels be normal, between the external and internal carotids and antenor to the glossopharyngeal and vagus nerves a fistula of the third cleft between the common carotid and vagu as well as between the glossopharyngeal and upon it larvingeal nerves, while a fistula of the tarth cleft mu t bend around the subclayran n the right and the arch if the aorta on the left in e these are derivations of the fourth aortic ar only in tula of the second brain hial left have been recognized with perfect rtainty (

with the ectoderm as a prominence in the ventral wall of the pharrin. It then becomes constricted to form a stalked vesicle and its stalk whose lumen becomes of offiterated persists for some time as an epithehal cord. The hollow stalk of the vesicle is the thyroglossal duct [57]. In a human focus of tive weeks we find this

and a numer tocus of new weeks we find this small vesicle on the back of the tongue. By the eighth week the first trace of glandular its ue appears. This is the developing thyroid gland which begins to secrete as early as the fourth feetal month. The gland slowly passes down to its normal resting place through the thy roglosal duct and this passage is obliterated behind it Normally nothing remains of this duct except the toramen carcium but when nature fails to do her duty a congenital abnormality is developed. If some of the thyroid cell are disjodged from the gland and remain along the duct these may devel pint accessors the roof. The thyroglosal luct may fail to be diterated either partially

Fig. 3. Branchiogenic cyst. New York Hospital. (Dr. Hartley.)

Fig 4 M ved enous and lymphangsoms (Johnson Surgical Dragnosis, Vol.)

or totally causing the existence of a fixtula or cvst (8)

5 Lymphatic cysts (lymphangioma-cysticum) The first evidence of the formation of the lym nhatic system is the development of symmetrical sucs in the neck which have been called jugular sacs. These are first found in the human embryo as endothelial lined sacs just lateral to the internal iugular vems. These fugular sacs become bridged or cut into by bands of connective tissue, this being the process by which each sac, originat ing from a pleaus of blood capillaries, is reconverted into a capillary plexus lymphatic in character Out of these lymphatic capillanes chains of lymph-glands are evolved. The ingular sacs and thoracic duct may be termed a primary system the secondary or peripheral lymphatics grow out from the primary system (Sabin 58) Many of the lymphangiomata are found in connection with the sutpres and features of the body Thus we recognize macroglossia (tongue) macrocheilia (gums, line) nævus lymphaticus (skin) etc.

6 Hemorrhagic cysts. Since the human embryo like that of all other verteinates, possesses a row of definite gill bars or visceral arches, experited distinctly externally by clefts, internally by entodermal pockets or pouches, so also its primitive vascular system is in conformity with this fundamental plan, and stroop branches, connecting the dorsal and ventral sorte—the aortic arches—each course in a visceral arch Six of these sortic arches are recognizable in a human embryo 5 mm, long. Our present knowledge of the viscular system in the human embryonists to the fact that normally the first two

sortic arches are lost, as far as their actual arch portions are concerned, but the third and left fourth arches are retained becoming the root portion of the internal carotid and acritic arch respects the Certain portions of the remaining arches are retained forming parts of the carotid the pulmonary arteries etc. the remainder of the arches normally disappear (57). Faulty retrogress to changes in a certain portion of one of these aortic arches account for the presence of or gental hemangiomats. Their situation all wave included the proposed to embryonic lines of fusion such as the facial to branchial deleta (col.).

7 Hygroma Embryologically speaking a hygroma so probably the result of fords sequentration of lympho d reats (10). It has also been suggested that its origin may be from the intercept of grant of the resolution of the sequentry of the sequentry of growth it has seemed best to consider hygromatic as differing from lymphatic Ohygromatic as differing from lymphatic gloromate as differing from lymphaticipomate.

8 Dermod cysta. Embryologically both expentration and tubulodermods may occur in the neck. In the first instance, a portion of surface epithelium becomes pinched off and continues to develop beneath the skin surface. In the latter case a portion of embryonic canal chranchial clott, thyroglocasi duct) remains patient and a mixed dermod results (60). Batul (2) restricts the use of the term dermoide to timons of the neck containing ectodermic inclusions, classifying as mucoides those representing endodermic inclusion. Kirmisson (14) also states that dermoids of the neck represent a retention of epidermal cells whereas mucoid

cysts are lined with cylindrical epithelium often

possessing vibrasae. o Carotid body tumors. There is little uni formity of opinion regarding the embryologic derivation of this body 5 mm, long 3 mm. wide and 2 to 5 mm. thick. Collison (9) states that it is of doubtful embryological derivation of undetermined function inconstantly present but occasionally giving rise to tumors of definite Funk (8) believes it represents the

remains of the upper part of the thymus anlage Many investigators such as Zuckerkandl (38) McMurrich (39) Stilling (45) Kohn (46) Keith (47) and others classify t with the sympathochromaffin system anlage which buds off from the central nervous system. Steide (48) Rabl (49) de Meuron (50) and others maintain that it represents an embryonal rest from the third or fourth branchial cleft, while Kastschenko (42) Paltauf (43) and Monckeberg (44) look upon it as being a connective tissue structure derived from the perithelium of the carotid arteries. It would however seem to be a well-established fact that this carotid body consists essentially of a loose connective tissue capsule and meshwork. containing chromaffin cells similar to those found in the medulla of the adrenals in the pituitary and in the ganglia of the sympathetic nervous system. Physiologically we have at present very little knowledge concerning this body mentally its action on blood pressure is contra The fact that it is not constantly present indicates that its function-if any-is unimportant. However we must remember that the different parts of the chromaffin system while of common embryology possess different functions. Thus the medulla of the adrenals affects blood pressure its cortex has an influence on the development of the sexual apparatus the pituitary seems to possess a trophic influence etc (o)

PATHOLOGY

r Branchiogenic fistula (a) Complete proximal (internal) portion is lined with cylindri cal epithelium (hypoblastic) the distal (external) portion is lined with flat pavement epithelium The hypoblastic portion also contains a layer of lymphoid cells in its wall The discharge consists of clear strings mucus or of a thinner milks or turbid fluid resembling thin pus. It may also contain particles of fluid or semisolid food

(b) Incomplete The lining may be wholly of cylindrical epithelium of flat pavement epithelium or a combination of both varieties

(c) Cysts. These have a wall of more or less

dense fibrous tissue containing lymphoid tissue

if the cyst arises from the inner embryonic They are lined with pavement epithelium or cylindrical ciliated epithelium, sometimes with membrane containing all the structures of the skin. They are usually unilocular occasionally multilocular Their contents varies it may con sist of clear serous fluid of mucus of oils material or of fatty material of solid or semisolid consistence. The walls may undergo suppurative or degenerative even malignant changes

2 Thyroglossal (a) Fistula The deeper portion of the fistulous tract is lined by ciliated epithelium that part nearest the foramen cacum

of the tongue with flat epithchum

(b) Cysts They are lined with flat or caliated conthehum

3 Aberrant or supernumerary thyroids the downward migration of the thyroid gland through the thyroglossal duct from the base of the tongue to its final location, some thy roid cells may become dislodged and remain along the duct (8) Occasionally the entire thyroid gland may remain sublingual and its removal be followed by myxædema (Murphy These embryonal 2) rudiments may be multiple, giving rise later in life to multiple gotters (Yakubowski 25) In general it may be stated that aberrant or supernumerary thyroids are subject to the same pathologic changes which may occur in the parent gland.

4. Hemangioma (cavernosum) These are always in the nature of fissural angiomata first they may appear as simple telangiectases when fully developed they present numerous large vascular spaces or smuses lined with endothelium, resembling the structure found normally in the penile corpora cavernosa

5 Lymphangioma Their structure is in most respects analogous to that of the hemangioma save that the vascular spaces contained therein are lymph channels instead of blood vessels. The supporting stroma in which the vessels are embedded may be fibrous fatty or mucinous the cavernous variety the lymph channels are very numerous and much dilated so that the structure on section has a somewhat spongs texture The supporting stroma is scanty thin delicate and transparent. Cysts varying in size from that of a pea to that of a walnut or larger may be produced. As in the case of hemangioma

6 Hygroma. These are usually large multi lobulated containing as many as one hundred The cyst walls are pockets in a single tumor thin and consist of endothelial cells supported by a loose connective tissue stroma. They are pecu-

ta lymphangiomata of the neck occupy or

originate at, the site of the branchial clefts

liar in having an independent power of growth sufficient to force them into the surrounding treaties (Dowd to) Some of them extend from the lower jaw to the clavicle and from the median line almost to the spinous processes of the cervical vertebra. They have a tendency to penetrate muscles (necudomalisment) many of them even pass under the clavicle and form an axillary cyst or under the manufrium to the anterior mediastinum (Kirmisson, 4)

7 Dermoid cysts. The majority of cases of dermold cysts reported were due to imperfect closure of the second branchial cleft. As a rule they are lined with stratified squamous epitheli um without other skin structures (epidermoid cysts) occasionally the cyst wall will also contain

hairs glands, and fat (dermoid cysts)

8 Carotad body tumor From a histologic point of view these tumors resemble endotheliomata or peritheliomata of the suprarenals (Lilienthal, 11) Their normal size varies from that of a grain of rice to a grain of corn. They reach a certain size when from 20 to 30 years old remain stationary for a time and then the con nective trasue only increases. The interlobular blood vessels thicken, with resulting sclerosis and atrophy

The consistence varies, but the tumor is usually moderately hard and elastic. In color it varies from a reddsh gray to a reddish brown. When present, the carotid body is found most commonly a little posteriorly to the bafurcation of the common carotid artery lying between the internal and external carotids, and more closely united to one or the other of them. It is attached to the one on which it lies by the lineament of Mayer through which it receives its blood supply nerve supply is abundant and is connected with both the cranni and sympathetic nerves receives branches from the vagus and glossopharyngeal superior laryngeal and superior cervical sympathetic ganglion.

Fibers pass from the vagus, glossopharyngeal, and sympathetic, to form a plexus in the angle of bifurcation just in front of the carotid body Many fibers from this plexus penetrate the capsule

of the organ.

These tumors may remain quiescent for many years. Lillenthal a case (11) was that of a woman 60 years of age who had noticed the tumor for 35 years. When malignant changes occur the growth of the tumor and infiltration of the carotid sheath and surrounding tissues may be very rapid. Funk (8) reports a tumor 8x5 cm. with pressure upon or involvement of the superior cervical sympathetic ganglion, causing contraction of the pupil on the affected side.

EASTLANDING

Subjectively there are absolutely no symptoms in the vast majority of these cases. If old enough, patients suffer from a varying degree of mental distress caused by the visible presence of a dufiguring tumor or fistula, they may complain of a sense of tightness in the neck, increased by excitement or overexertion in the case of multilocular hypromata they have reported a gurgling sound on coughing (due to compression of one cyst by the sternomastold forcing the fluid content into a neighboring cyst) cysts may however become inflamed or infected. giving rise to the common subjective findings of acute or subacute inflammation.

In a case recently operated upon by the revacwer the patient a woman 72 years old, with an incomplete internal branchial fistula (see Fig 1) had all her lifetime been obliged, after each meal, to evacuate the contents of her cystic fistule into the pharvnx, semisolids and liquids being forced into the sac during each act of digiutition. Notwithstanding this repeated traumatism, it was only within recent months that the fistula had become infected occluding its lumen with subsequent putrefaction of the contents of the cyst. The inflammatory symptoms alone, brought her to the operating table. Of special interest are the subjective symptoms of imperfect closure of the upper portion of the thyroglosial duct forming what might be termed an exaggerated foramen crecum. Dr T W Lewis of Chicago has reported (but not published) several such cases. The patients suffered from spannodic cough and irritation of the pharynx which was relieved only by cautemation of the foramen usually to the depth of one-half to three-quarters of an inch. In every case re ported by Doctor Lewis touching the opening of the foramen occum with the tip of a probe in variably produced an attack of severe snarmodic coughing

Even carotid body tumors give rise to few subjective symptoms until they begin to infiltrate the carotid sheath producing pressure symptoms on the vagus, superior laryngeal, and superior cervical plexus of nerves (disturbances of phona tion dysphagm dry cough, deafness, conjunc tivitis)

Objective (a) Fistula. If of the second branchial cleft, the external opening lies in the akin of the neck, between the anterior border of the sternomastoid muscle and the median line anteriorly and between the greater cornu of the hyord bone and the sternoclavicular foint of the same side. The external opening is usually very small often so small as only to admit a fillform guide or a bristle. The inner openling lies in the neighborhood of the tonsil in the lateral wall of the pharynx, or near the pillars of the fauces. In the complete fistula, it is sometimes possible to inject fluid through the external opening into the pharynx the passage of the fluid into the pharynx may be recognized by the patient by its taste or by the surgeon by its color (strychnine quinnie milk or methylene blue solution) (60).

The discharge from a complete fistula is a thin clear mucus that of an incomplete external is thicker and more turbul while the incomplete internal variety discharges a thick mixture of mucus and epithelial or endothelial elements admixed with particles of more or less decomposed food

A instula of the thyroglossal duct is always median between the lower margin of the broad bone and the sternal notch. Branchiogenic cysts are single soft freely movable not tender (unless recently inflamed) and are never in the median line. Thyroglossal cysts are usually maller and always in the median line. Collisonand MacKenty (6) describe the objective findings of a carotid body tumor as follows.

1 Early A tumor varying in size from a kernel of corn to a robin's egg situated under the sternomastoid or at its anterior margin. It is egg shaped single discrete firm elastic moves easily laterally but not vertically is pulsating (but not expansile) and may give a bruit on ausculation

Late Paralysis of vocal cords (due to in volvement or recurrent larvageal nerve while its libers are still within the vagus) difficult phona tion and degluttion congested larvax irregular pupils with no reaction to light on the affected id, lessened mobility of tumor loss of weight

and progres is e cachega (a)

F. Matthews (b) reports a case in a man sears old of presenting hematrophy and paralysis of the tongue in addition to other classical indigns. The left side of the pharvia was pushed inward and the left tonsil occupied a position near the median line.

DIFFFRENTIAL DIAGNOSIS

O C Smith (6) has worked out a very exhaus tive outline of tumors of the neck which the reviewer appends in full

The true nature of a instala of the n sk can be ascertained readily by inquiring into the hi tory of the case. Only branchial or thyrogits all n tu lie are congenital. Tubercular adentitis late car cinomata or sacromata and is implangiomata or hygromata; the last two only as the result of exploratory puncture or trainmatism in any give rise to fistulae. Cysts of the neck must be differentiated from the following. (1) cervical lymph adentitis (2) carcinoma (3) sacroma (4) throma (5) lipoma (6) Hodgkin's disease. (7) syphilis (8) aneurisms (9) aberrant or supernumerary thyroid (10) carrold body timor.

TREATMENT

The correct treatment of congenital deform thes of the neck is to leave the benign cases alone unless their removal is desired for cosmetic reasons or on account of inflammatory pressure symptoms and to remove early and radically growths having a malignant or pseudomalignant tendency such as lymphangiomata hygromata and carotid body tumors. It should become axiomatic for instance that a solid tumor of long standing situated in the anterior triangle of the neck at or near the level of the lower border of

the thyroid cartilage, should be looked upon as a possible caroud-body tumor and removed before it involves the surrounding structures par ticularly the carotid sheath. The general modus operandl is essentially that of the radical removal of tubercular glands of the neck. Bearing in mind the probable embryologic derivation of the fistula or tumor one should resort to a careful desection of the growth while constantly bearing in mind the tissues and structures which are to be avoided. In the extirpation of hemangiomata, the reviewer has made use of congulene Kocher Fonio in order to minimize hemorrhage (61) A 5 to 10 per cent solution is injected around the base of the angioma just prio to its excusion. Extirpation is much facilitated thereby The radical extirpation of a complete branchiogenic fistula requires poinstaking care A small probe or urcteral catheter (Dowd 51) may be

passed through the external opening as far up as possible. A circular incision is then made around its external margin so as to leave a disk of skin around the stoma of the fistula. This is followed by the usual oblique incision parallel to the anterior border of the sternomastold, including skin superficial fascia and platysma. The sternomastoid is retracted outwardly and the dissection will proceed easily as far as the bifurca. tron of the carotids. From this point on no sharp or pointed instruments should be used. The final dissection—up to the pharyngeal wall becomes a slow process of teasing out the fistula from the surrounding tissues. With the patient a mouth held open and using a head murror tugging on the fistulous tract will cause a dimpling in below the tonsil or on the lateral pharyngeal wall. Having freed the entire tract one of three procedures may be employed to

complete the operation | I on Hacker (54) cuts off the fistula three-quarters of an inch from the pharvngeal wall. An eve probe or small catheter is then pushed through the fistula into the pharvnx and sutured to the distal end of the tract By traction through the pharynx, com plete inversion is obtained. The stump usually separates or tears away readily from the mucosa The opening thus left is sutured with catgut Wishing to preserve the entire cyst and tract in one of his cases the reviewer proceeded as fol lows Having dissected the turnor up to the pharvngeal wall two clamps were placed on either side of the tract in such a manner as not to oc clude its lumen. A third clamp was then placed squarely across the neck of the tumor just distal t) the guy clamps and the mass removed in toto The remaining fistula was then cauterized with pure carbolic acid and a catgut ligature thrown around the guy clamps proximal to them and tied. The clamps were then removed and the incision closed without drainage. The result was perfect. For those cases where adhesions to the circuit sheath make complete dissection impossible or extremely dangerous. Koenig (34) has devised an ingenious method of treatment. He frees the distal end of the instulous tract as far as he can and then passes this free (distal) end through the mucous membrane in front of the tonsil and stutches it there thus leaving a curved sinus with an internal opening at each end—tile.

Thyroglossal fistulæ or cysts should always be injected with methylene blue and every par ticle of stained tissue removed. The usual procedure has consisted in shelling out the cyst as far as the hyoid bone. Inasmuch as the tract invariable passes either through or behind this

bone, cures have only been affected in those cases where the duct is represented by a fibrous cord proximal to the hyold. Recurrences have been the rule. Mckenty (13) mentions one case where three successive operations were necessary even then he does not state whether the third operation was a permanent success. Chisel ing or drilling through the hyoid bone, followed by cauterization, is recommended in obstinate CRSCs.

The extreme thinness of the walls of a hygroma. makes a clean desection of the entire tumor almost a surgical impossibility Portions will tenr and remain behind, leading to extremely rapid recurrences. Dowd (10) operated on a girl not quite three years old removing the cyst as far as the sternum It promptly recurred and at the second operation he was obliged to extend his dissection as far back as the scaleni muscles This case died on the tenth day from shock and harmorrhage. A preliminary injection with methylene blue is absolutely indicated in these

CRECE. The operative mortality of carotid-body tumors is formudable. Collison and Mackenty (o) collected 60 cases up to the year 1913 Of these, 54 were operated upon In 4 cases, the operation was merely exploratory in nature in 32 the common external and internal carotida were ligated in 7 only the external carotid was ligated in 15 cases the tumor was dissected away from the blood vessels or dissected away from the internal carotid or the common carotid after ligation of the external. Recurrences occurred in 6 of these 15 cases wherens only 2 recurred after complete removal of all the carotids. Im mediate death occurred in 12 cases of the 42 who convalenced 4 had prompt recurrences and in 6 other cases speedy deaths were in prospect from recurrences known to have existed when the cases were reported. We thus have an operative mortality of 25 per cent and a prospective mor tallty of 40 per cent, a far from encouraging outlook. Desgouttes (1) reports the successful removal of a tumor en bloc with the internal jugular vein and the pneumogastric, the internal caroud being saved. He has also successfully removed the pneumognatric the sympathetic plexus, the internal jugular and the internal carotid in another patient. He does not state however whether or not either of his patients succumbed to recurrences. Lillenthal (s) ligated and resected, above or below the tumor mass. the internal jugular and all three carotids, saving the pneumogastric. Twenty-four hours after the operation his patient developed central

aphasia and right hemiplessa. There was no aphonia but the left eyeball softened and its pupil contracted. All symptoms except the contracted pupil disappeared in a few days. He ascribes the pupillary contraction as probably due to injury of the superior sympathetic cervical. ganglion. It is therefore self-evident that a large percentage of these tumors will be considered inoperable by conservative surgeons. If seen early desection away from the caroted befures tion leaving the vessels on sits has been sur gested (a) in all other cases if operation is under taken, the mass should not be dissected away from the blood vessels but the carotids and internal jugular vem should be removed en masse after freeing the nneumogastric

ETTLOGATEV

The pre-operative diagnosus of congenital deformaties of the neck is all too seldom made. A careful history and examination of the deformity oftentimes aided by the injection of either bitter tasting or coloring substances, will enable the surgeon to make a correct pre-operative diagnosis.

2 No operation should be undertaken unless the surgeon is prepared to carry the same to a complete conclusion. Partial removal of a secreting wall is worse than leaving it in silu

3 The desirability of operating on carotidbody tumors must depend on (1) a very early diagnosis, while the tumor is still benign (s) in late cases, on the desperate nature of the patient s symptoms (paralysis of vocal-cords stenosis of pharynx, hemiplegia, hemiatrophy paralysis of tongue, etc.)

ABSTRACTS OF CURRENT LITERATURE

GENERAL SURGERY

SURGICAL TECHNIQUE

OPERATIVE SURGERY AND TECHNIQUE

Grant, W.W. The Immediate and After Treat ment of Railway Injuries. South. If J 9 6 ix, 157

The droumstances, conditions, and environment of rullway injuries are unavorable to the best treatment so that tentative measures only should be used until the potient is in more I would surroundings. The immediate application of by dropen percode and loids with dry steril graze is recommended for wounds Fractures should be temporarily immobilities.

Hemorrhage is a common condition in railway injuries and many times is incorrectly treated. Pressure to stop the hemorrhage should be used for as short a time as possible as tissu necrosis and subsequent sloughing may result from prolonged anemia f the parts.

Shock is frequently unscientifically treated and its presence many times disregarded. No serious operation should be perf med in the presence of shock. T combat shock dry heat applied to the body hypodermodysts, rectal saline, and sugar solutions are recomized seems.

Fractures abould be treated if possible without the open method especially should all compound fractures be left alone as regards surgical approximation of the fragments, for at least ten days or two weeks following the accident

Conservative surgery as regards feet and hands is very important. Ragred wounds abould be left open t allow free drainage Musicles, tendors, and nerves abould be carefully emplored and all fractures should be carefully emplored and all fragments and bone débris abould be removed. J. H. Sanza.

Barciay, A. E. Preliminary Note on New Method of Bullet Extraction. Arch Rediol. & Electrotherap. 9 6 xx, 359.

Barelay method is an elaboration of the schem of marking the location of foreign body by insert ing a large needle int the tissues until the body is reached, using the fluorescope to guide the needle. Instead of inserting a needle he uses two promps, one longer than the other the point of the shorter prong fitting into th depression near the point of the longer one to make the insertion only. of the prongs have handles arranged at right angles to avoid the screen and mad. If he arranged can be opened and closed. He has also arranged his instrument electrically so that a bell rings when metallic body is in contact with the prongs.

Fourteen cases are reported in which the foreign bodies were removed with a small skin incision and without the mullistion of tissue usually required in such cases.

Catheart, C. W. Methods of Preparing Sphagnum Moss as a Surgical Dressing. Leact, Lond., a 6 cm. 520

A description is given of a simple and economical method of sterilisting phagnous moss. The absorbing qualities f th moss are superior to exten wood. The moss is first picked clean of grass and leaves in suitable quantities are placed in small handlette bags which are immersed in bichloride to be which are immersed in bichloride fourth of the per cent of the property of the property of the per cent of the per c

H. G SLOAM

Torey D W The Nerve Supply of the Lower Abdominal Wall as Related to the Pfannenstiel Incision. Am J Surg. 916 xxx 145

Special care should be taken in any bdominal incision not to injure the nerves supplying or crossing the cut structures, since such nerve injury predisposes to hermia by causing paralysis of muscle or atrophy from disturbed nutrition or loss of sensafrom

The course and distribution of the nerves of the lower abdominal wall are described, especially those which may come in the field of a Pfannenatical incision, principally the anterior divisions of the twelfth docasi and the hypogastri branch of the first lumber.

In the Pfannenstiel incision, after the aponeurous has been separated from the muscle and the lines alba divided and the upper flap retracted, two or sometimes four large nerves can be seen coming up from the recti about an inch from the median lin

and purcung the anterior fascia. These are the anterior divisions of the twelfth dorsal nerve. They are often half as thick as a match double and ac companied by a blood vessel. They should not be cut as in retracting the upper lap they can be drawn out sufficiently in nearly all cases. The cutting of these nerves ac ording to Tovey may account for the reported cases of herria following the Pfannenstell incision.

LUCIV M. LUNDAY

Modernan A. The Prevention and Treatment of Some Obscure Conditions Complicating Convalencence After Gastro-Enterostomy Ga gow M J 1016 hxxv 3 3

MacLennan considers the undesirable sequences of gastro-enterostomy and describes an operation by the adoption of which these sequelæ may usually be prevented. The steps are as follows.

- I Except in infants the new stoma is made on the pylone side of the lowest point of the great curvature
- 2 The colon is raised so as to display the mesocolon that area which is freest of vessels yet contiguous to the selected spot on the stomach wall is divided vertically to the necessary extent
- 3 The stomach is drawn through the sht in the mesocolon and clamped perpendicularly occasionally with a slight inclination toward the pylorus but never with the in lination toward the left. The omentum and colon are then returned into the abdomen.
- 4 The bowel to be attached is emptied by digital pressure and clamped when flat
- 5 One continuous Lembert suture (silk) unites the two surfaces along the line which is sackle-shaped at the lower end and which is just off the free edge of the bowel. At the end of the line the thread is hitched under the last loop and caught lightly in a pair of pressure forceps so applied that the serra tions of the forceps cannot cut the lik.
- 6 The stomach is opened and a small circular section is removed from the entire thickness of the wall corresponding to the curn sture in the line of the Lembert suture making a racquet shaped opening. The same is done to the bowel but on no consideration is the mucous membrane of the latter excited in the shit part. The redundant mucous membrane as the upper part of the stoma offers some impediment to the entrance of bile while the cutting out of a section of stomach and bowel leads to the formation of a gaping hole over the mouth of the efferent jejunum and facilitates evacuation of stomach others.
- 7 The operation is concluded by suturing the openings together with catgut and then continuing the Lembert suture with has been laid aside. We little of the girth of the bowel is taken up as possible. The junction is pla ed inside the lesser peritoneal cavity by uniting j junum to the opening in the trans ence mesocol in for the greater safety thus gained in localizing possible leakage.

In the author s opinion bleeding from a duodenal

or pylone ulcer forms the sole indication for closure of the pylorus. Where hæmorthage has occurred all large vessels going toward the ite of the ulcer are ligated. Closure of the pylorus has no influen e in preventing bilious regurgitation.

Following gastro-enterestomy morphia is allowed during the first twenty four hours only The Fowler position is used rectal saline is given every four hours, a dessert spoonful of brandy and glucose on raisin tea being generally included During the first twelve hours nothing is swallowed though the mouth is frequently washed out with ice water During the second twelve hours sips of water acidulated with lemon juice are given eviry quarter During the next twenty four hour the water is increased to a half oun e-while during the latter part of this time dessertspoontule of butter milk are given. On the third day the diet consists of beaten curds butterfully lemon tea coffee with out milk and sugarless stewed apples. On the fourth day calomel is administ red (about 3 grains) in one half grain doses every quarter hour This is followed by a suds enema containing asafortida, quinine or turpentine. Three daily scrambled egg banana and cream malted milk or fish cream in addition to the sour milk, apple etc is given Thereafter the diet is gradually increased until at the beginning of the second week fruit (cooked or uncooked) chop fowl and fish are included sour wine may be taken advantageously with the meaty meal, but fresh milk after gastro-enterestomy must be avoided Bilious regurgitation without vomiting in cases with urgent symptoms requires the stomach tube After siphoning the stomach should be washed out with warm water and a few ounces containing a tablespoonful of vinegar left in. Small doses of opium or better one twentieth grain of heroin may be given thrice daily to encourage gastric contraction, and retard the secretion of bile

The mechanism of bilious regurgitation is well called a vicious circle for the presente of bile induces conditions which encourage its continuance. In the presence of alkali the stomach relaxes and the extra weight of the fluid increases the sagging of the organ whose capacity for holding bile is further enhanced. As the overfilled organ sags it inclines to close its exit by obliterating the lumen of the jejunum. The position assumed by the patient then becomes of importance in so far as it may relieve a downward pressure Under these conditions also vibratory massage is efficient. Heat is comforting and assists in the return of gastric tonicity. In the acute states of regurgitation, champagne to 4 ounces will speedily produce amelioration. A peppermint liqueur is excellent for occusional bihous r gurgita tion. ALBERT LITRE PRICE

Weeks A. A Simple Method of Giving Solutions by Bowel | J. 4 m. M. 4 | j. c. 1

After numerous experiences in watching the routine use of the Murphy drip after oper tions in various hospitals the author came to the cond-onthat half if the distress complained of by patients is due to the retention in the bowel of gas or too m ch fluid. This is especially so in little children.

For some time h has used a method which conaits of the usual container and dripper supplied by all hospitals with small glass founds a lunnel holder which will fit on the container stand Sfeet of rubber tubing, with a glass tip and an ordinary rubber catheter t suit the case. Th funnel hangs on a level with the patients abdomen The container is lung so that the dripper will dup i to the funnel. The solution is allowed to dup only as fast as it is absorbed, and it is not necessary to keep it warm. Even to Comercia

ASEPTIC AND ANTISEPTIC SURGERY

Emery W D A Standard Method of Teating Antiseptics for Wounds, with Some Results. Lance, Lond., 9 6, crc, 8 7

The uthor has aimed to test antisepties under the same conditions as when they are ordinarily applied to wounds. He uses blood as a medium because of the presence of blood in all first wounds, and further because pas which would be the ideal medium is difficult to obtain if a unif me type. Washed corporates were added to an equal amount of serum so that there would be no dotting while the

experiments were being carried on. He used the streptococcus facults in testing the notency of the various antiseptics because it is the chief enemy in wounds it can always be brained in pure culture t grows rapidly so that the results can be secured in twenty four hours and furthermore it readily emulsifies so that there are no masses t resist the action of the antiseptic. In the uth technique he uses nine parts of blood and ne part of 18-hour culture of the streptococcus, containing about 50,000,000 cocci per ccm. This sol tion was thoroughly mixed with an equal qua tity of the antisentic to be tested o a class slide Equal por tions of this mixture were then sucked into two capillary pipettes and the ends scaled. Pipettes were then incubated, one f fifteen minutes and the other for one hour and at the end of this time two loops from each pipette were inoculated the surface of an agar pi te. These plates were then

after twenty four hours.

Som antiseptics show fewer colonies after fifteen minutes than at the end of a hour because of their faculty for combining with the protein in the medium in which the becteria are mixed. This neutralized thou of the mathieptic with the protein has very near by passed off the end of an hour so that the remaining bacteris founds more this later period.

incubated and the number of colonies determined

Emery found that by this method Dakin a solution was only one-seventieth as powerful as carbolic acid. It was one-fortieth as powerful as binlockide solution, one thirtieth as strong as sysol, and onetwo-hundredth as strong as malachite green. Unfortunately the action of this last antiseptic on the living ells is too powerful for clinical use.

The end result of any antiseptic, in wounds, is a combinant of its action on the interling bacteria, coupled with its action on the fixed body these cells. This latter fact rethe author has been nable so far to determine accurately be the is working on this problem. HARRY O SLOW.

AN ESTHETICS

Stanley L. L. Spinal Ansestheria; Analysis of Two Hundred and Eighty Coses. J Am. M As n 6 ltvl. 200

In the 80 cases in which spinal angesthesia has been used on the immates at the San Quentin, Cal., person tropacocain in 5 gr doses has been the agent employed

In outlant operations excepting those in which the bdommal viscers are handled no hypnotic is go en the petient before the operation. The patient walks t the operation on and mounts the table. With one min t be feels that his feet are becoming warm no the may even feel a singling sensation in his toes. Within tw minutes, sensation is lost about the suns and, as a rul within bout four min tes the loss if sensation is so great that opera tions for herman may be done without pain. For operations above the umbillicus the patient is all level to stay in the Trendelmburg position for

I wed to stay in the Trendelenburg position for six seven munits, it apparently it takes that long if the tropsoccalin to gravitate explained to best the nerves which supply these segments. Some provided that the second section of the school position has been a minute or personal colour position has been a minute of the second section on the ser turn 4 minutes for bernas 3 minutes and for gastro-enterostomy 4 minutes.

The conclusions are as follows

In this series of So cases there has been no fality

There has been comparatively little shock.

3 There has been headach in only 8 per cent of cases.

4 There has been no p eumonia following the operation.

5 There have been very few post-operative complications.
6 There have been no permanent paralyses fol-

lowing the amesthetic.

7 The period of co valescence has been short ened.

ened.

8 With the relaxed muscles, closing of the abdo-

men is greatly facilitated

o. The blood pressure has fallen in most cases
but in the verage case not to a dangerous degree.

10. The height to which the anaesthetic is effective is influenced by the length of tim the patient is in the Trendelenburg position.

II The pulse-rate is not influenced to any marked degree by tropacocal intraspinally administered.

EDWARD L. CORNELL

Mahn G: Proctical Notes on Local Angethesia in Otorhinology (Notes oratiques sur l'anesthesie locale en oto-rhinologie) An d mal d Pere lla d du la ver Par 1016 tl 845

In most interventions in the frontal and max illary sinuses or in the ma told not alone must the supertial layers be anasthetized lut also and especially the bony walls internally as well as externally trepanation of this avities being usually followed by urettage. In order to obtain this result the author says that it is necessary and sufficient that the injection should be rushed into the exterior periosti laver. But the will be more perfect if a large part of the periostic surface inveloping the cavity is injected

The author uses a novocaine solution and three hours pri r to its use he makes a hypodermic in jectu n of pantopon or morphine His technique is II & BRENT IN myen in detail

Kroenig B and Siegel P W Shockless Surgery with the lielp of Paravertebral Ancesthesia and Scopolamine and Narcophin Gynec & Obst o 6 xxxl1 5 4.

Kroenig reports 670 cases of gynecological and obstetrical operations done under paravertebral ancesthesia at the University Frauenklinik in Frei burg G rmany

The method consists in blocking the nerve trunks directly at their exits from the intervertebral foramina or from the sacral foramina for the sacral nerves with a one half per cent solution of novocaine suprarenin tablets \ \ prepared by Hoechst Farbwerke The anæsthesia is preceded by twothirds to one gram of veronal on the night before the operation and o coos gr scopolarnine and o os gr narcophin two and one fourth and one and one half hours respectively before beginning the anaisthesia. and half a dose of each one half hour before anes thetization if the twilight sleep is too light. For cachetic patients or patients weighing under one hundred pounds the dose is reduced to o 000225 gr scopolamine and o 0225 gr narcophin respectively and o coors ar acopolamine and o crs ar narcophin for the last dose if necessary The anarsthesia con tiques uniform from two and one half to three hours and operation may be begun from fifteen to twenty minutes after anasthetization

The complications noted are of minor importance and may result from the condition of the patient or from the operation itself. No deaths resulting from the angesthesia were noted. In attempt was also made to eliminate post-operative pain by dust ing a powder called anaesthesin into the wound as it was closed by layers Apparently a reduction of pain was accomplished in most cases and in some there was a complete elimination of post-operative pain but the resulting cedema in the wound and retardation of healing seem to be factors that more than outweigh the slight advantage gained and the use of this powder has been discarded for the present

I receding the anasthesia with scopolamine and

narcophin climinates the psy hic shick due to the preliminaries of an operation, and puttints oftin have no recollection of e at from the time that receive their veronal on the night before parati n until they recover full consci u ness three to ix hours after the operation

The variety of operation time under this form it anaesthesia indicates it gin ril appli libity in general surgery as well as in gyne of gy in Lobstet ries and the success of the liviling lim warrant a fair trial by the profession. The te hin jue is n t as difficult as it might sam in l require only a definite knowledge of the listril ution of the nerves or working according to tall so and belonexperienced users of them, thou

With the eliminate n of the post-operative pain upon which problem the Freil uig limi still wirk ing the method prounts the ill all tem finance thesia. Its chi f alvantag he in th uniformity of the angesthesia of tained in lin the lack it serious immediate or post anæstherr complications

SURGICAL INSTRUMENTS AND APPARATUS

Thompson G S Some Surgical Uses of Celluloid Brit J S rg 19 6 m 696

Celluloid used for surgical purposes varies in thickness from that of ordinary ph tography films to that of thick cardboard. In cases where it is desirable that it become encapsulated it should be perforated with pun h holes throughout When infection does not occur the celluloid does not provoke irritation of the tissue sufficient to cause subsequent sinus formation or the extrusion of the celluloid. The celluloid is sterilized in the autoclave or by boiling. If crinkling is to be avoided the material must not be boiled for a long period

It is not an absorbable material Thompson suggests that elluloid might be used to advantage in the various types of hernise. The precautions necessary to be observed in its use are pointed out by the author In femoral hernise the plate should be triangular in shape and should be provided with a flange on its outer border where it comes into relationship with the femoral vein. The plate for inguinal hernize should be roughly elliptical and should have a gap for the passage of the cord at its lower border. In the skull thick plates are used fashioned to suit the aperture. Perforations are avoided Celluloid will be found preferable to other material such as transplanted bones — phalanges pieces of rib etc in plastic operations on the nose for restoring the bridge Thompson suggests the possibility of using cellu loid caps for the ends of bones after certain opera tions. For this purpose he suggests that there be kept on hand a series of casts and molders in differ ent sizes corresponding to the commoner joints involved. The celluloid is softened and applied to the cast and it is then worked into shape with the molder The whole is then placed in cold water to harden

It is suggested that celluloid be used for medullary pegs after fracture. The advantages claimed for the medullary peg of celluloid are it is not brittle it gives perfect alignment does not instrere with outcogenesis, and therefore does not favor nomin causes only slight disturbance to parts causes no disconfiort to the patient it requires only a minimum of trauma for its introduction the operation is mapid. In the author's opinion the

alleged defects of pegs do not exist, and granted correct technique, gratifying results may be anticipated. He believes that this method is destined to supersede the others. Spins blids is a condition in which ideal closure of the gap can be made by a properly shaped celllold plate. A flame-proof celluloid known as "taxuloid" is now on the market. Inputs Comp.

Johnson, G. C. Fracture Splints. Lescet-Clie o 6 xvd, 573

The other uses the as material for splints, and believes it most practical especially for the country practitioner. The tin splint is most advantageous because it is light in weight, is firm and strong is capable of being modeled, and can be sterilized.

SURGERY OF THE HEAD AND NECK

Von Hacker The Plastics of Penetrating Cheek Defects Due to Gombot Injuries (Plastic bei penetrieranden Wangern Defekt und nachfolgender narbeger Kleferkleume Imbenonders nach Schneverlatzungm) Belir him Chin 9 ft wruh, 89 von Hacker's method of remedying defects of the

cheek due to gunshot wounds is divided int two stages.

when the first stage an Israel stap is cut from the best down the neck commending dose to the defect but in such as way that a strip of atin is left between the defect and the slap. This strip is termed it bridge. The stap which hangs from the cheek, is turned over passed under the bridge, and part of it covered over the defect. This is sutured to the edges of the defect and the former outer skin surface of the stap thus forms the interior lining of the mouth at the defect. The edges of the days plut are approximated defect. The edges of the Sap plut are approximated

The second stage of the operation takes place when the flap has headed in the defect. This consists in severing the lower edge of the bridge and with this and th unused portion of the turned over skin flap matching over the extremal surf co of the defect and

approximating edges

The author illustrates his procedure by several diagrams clearly showing the steps I the operation. He also shows some photographs of the excellent allowing the flap to be noutlished during the healing process prevents necrosts and is thus superior other methods in use.

The utho describes in detail the method of making a plaster cast of the nose in deformities thereof

An attempt is then made to correct the deformity by one or more procedures. Submucous reaction with straightening of the nasal bones may give the result dealred. When depressed areas are prese t a piece of cartilage from a rib may be inserted to fill out the nasal coston. When unsightly projections are present these may be curetted off subcutaneously with a special spokeshave. An injection of parafin must sometimes be resorted to finally I H. Sruxs.

Vilvandré, G. Radiography in Gunehot Wounds of the Skull. Arch. Radiol & Electrothersy 9 6 xx, 306

The point which the author wishes to emphasize is that owing to the bad prognosis in lesions in which foreign body has bodged in the brain, no operation should take place on a skull which has not been previously radiographed to ascertain the presence or absence of a foreign body and its careful localization.

To trephine a stall for depressed fraction will of course give reinel but a patient with a build or piece of shrapped in his brain will, sith perhaps a few remote exceptions, die within six months of cerebral absence. The only except in which might be allowed is that in which the builder is not distorted through a previous riccocks and is in all probability septic. The first point can be determined by the N-ray House E-Perriss.

Lee, J. R. Removal of Intracranial Foreign Body Under X. Raya. Brit. If J=0 6 i, 447

Attempts to locate piece of shell in the occipital be with probe or to remove it with an electromagnet having been unsuccessful, the \(\) ray screen was tried. The operator was clearly able to see a probe which had been passed in along the track and the fragment which had been pulled forward by the magnet and was caught in brain rassur. Removal of the fragment was effected by means of a crocedile forceps passed along the track to a depth of four inches. Noting the relation of the fragment to the firstrument during the process of removal may prove of material assistance.

L. K. ARMSTROVO.

Whitaker R. Gunshot Wounds of th Cranium. Bu J Sarg 9 6 fil 708.

The uthor review the results of his observations on 106 cases of cranial injuries which have been received for treatment from seven to ten days after the injury. Or this number \$5 were penetrating or perforating wounds of the brain

The operative treatment originally advocated by Sir Victor Horsle was the method of procedure adopted in these cases. It is in the main as follows 1. The injured and septic area of the scalp must

be freely excised

2 The injured area of skull must be freely exposed by suitable incisions and turning down suitable flare.

3 \text{ ormal dura mater must be freely exposed around the entire circumferen e of the wound which it penetrates by a wide removal 1 bone. Foreign bodies blood and pus mus be removed from the brain without breaking down protective addessions. The whole wound must be left open from the first.

In yound, where the bullet has perforated the brain the wounds of entrance and exit must be treated alike. When the wounds of entrance and exit are lose to one another the two openings are joined - a new factor that of decompression is appreciated in the treatment of these cases. It soon became apparent that these cases did better than those in which the wounds of entrance and exit were not so close together. Cerebral hernix in these ases did not become strangulated but ultimately retired inside the dura mater which in the end became slightly concave has made it a pra-tice to remove those foreign bodies and fragments of bone which are obvious but he has not searched at length for them, as he has found that the brain is far more able to take care of itself in this direction than is ordinarily believed.

The length of time taken for the operation is an important factor in preserving, the patient's life Speed and free decompression have been the dom inant ideas in these cases. The type of infection has been an important determining factor. Streptococcal infection has been fattal in op per cent of cases. It is not usually associated with the formation of adhesions the herma grows rapidly and is not co ered by a protective membrane. In the cases, howing a staphylococcal infection the patient makes an amaring high when death occurs it is due to infection of the ventricles through a narrow track. These cases show a marked protective covering for cerebral hernite.

As to the technique employed, chloroform and oxygen have been given. The local preparation of the scalp consist in washing with petrol, with methylated spinis and then with lodine. From the beginning of the operation the wound are is continuously irrigated with 1 to carbolic. Bleeding vossels are ligated but forceps are left on for twenty four hours. Bleeding from the dura and sinuses are dealt with by muckle grafting.

The muscle graft not only erves to control be most hape but it erves as a center for granulation formation. When the bony parts are removed the irregating fluid is changed to hydrogen peroxide all obvious foreign bodies are removed and the

Jackson H Craniopharyngeal Duct Tumors. J. i.e. M. 4 1 1 12v1 4

Jackson reports one case and ret is o cales collected from the literature of tum roll ansing from rests of embryonic tissue along the craniopharyneeal duct

These rests of buccal epithelium high may occur within the persistent canal and at the manual extremity of this canal in the region of the infundibulum and anterior lobe it high pophysis magive rise

to cystic or solid tumor

These hypoph are duct tumors he in the median line at the base of the brain bounded anteriorly by the optic chiasmus posteriori by the pons above by the floor of the third entricle and below by the sella Laterally they may encroach on the cerebral peduncles and temporal lobes. The circle of Willis usually surrounds the tumor The hypophysis itself may be found intact or be pressed against the floor of the sella. The first five cranial nerves may early undergo a pressure atrophy but the olfactory nerves usually escape The foramen of Monro may be occluded and internal hydrocephalus may result. The optic tracts are most seriously affected and may be spread out on the tumor like a ribbon. The sella is usually normal in size or only slightly enlarged. The tumors are usually the size of a pigeon or hen s egg when discovered. The majority are cystic when solid they show areas of cystic degeneration. The author describes the histology in detail.

Of i cases in which the symptoms are clearl stated the were associated with adiposit and other symptoms of the Froetich syndrome such as genital dystrophy and loss of body hair. In 6 cases, to had symptoms of failing vision and its of brail pressure. Optic atroph, was noted in the cases. The chinical course is a risk some lasser is a bit a cut.

st ge in three or four weeks, others have symptoms for years.

for years.

N case reported has been associated with acromeraly

In regard to disgnosti, roentgenoscopy is usually negative because the sells is rarely enlarged. The early disturbance of vision and one or m re symptoms of the Froelish syndrome, especially disjoistly will suggest a tumor of the hypophyseol region po per cent of these are candiopharpaged duct tumors. The finding of cycl at operation with the referencepic demonstration of stratified eitheli more considerable.

I be buccal type completes the diagnosis. If drainage of the cyst type can be maintained, the patient can live for an indefinite length of time. If the cyst continues to enlarge biloniess maniferential from pressure on the optic tracts r chiasm and death follows in a f w mouths or years from brisin pressure. On the whole the outbook for this type I t mo is bad as it is practically impossible; the separate the cyst wall from the surrounding brain.

structure.

Three operations were performed by Kanavel by the transsphenoidal root the nose being reflect eli upward. The anterior wall of the cyst was removed together with some blood-stained fluid. The patient is taill living one and half years after the last operatin, and there has been no return farmer to die.

E. H. Poox.

Royce, C. E.; Sarcoma of th. Boss of the Skull. J. Am. If Ass., 9 6, levi, 188.

Reported cases of sarcoma of the bones of the base of the skull are not numerous. Of twenty sarcomat in this region, 60 per cent occupied the middle force. They rurely progress toward the brain but invade the bones and sometimes send processes into adjoining sinuses. Disturbances of the cranial nerves gradually appear d to growth about the nerve-roots. Sarcomata tend to involve one skle only if bilateral they are almost always carrinoma or endothelioma exceptionally bilateral growths may be fibrosarcoma or very malignant sarcoma. The thor quotes Cant nnet s case of sarcoma of the sphenoid and reports a case of his own. In the latter there had been complaint of headach and disturbance of vision, ophthalmic examinatio showing optic neuritis with evudate Decompression revealed nothing but increased intra cranial pressure. At necropsy an encapsulated mass o cm. in diameter was found intimately connected with the periosteum covering the sphenoid bone Section showed cells of spindle-shaped type, mitotic figures not being numerous, and tumor cells everywhere separated by reticulum of conective timue. Amberg, E. Conduction Ansesthesis in a Case of Brain Abscess. T Am. Om. Sec., Washington, a 6 M v

The patient, 37 years old had been ill for about ten day with severe pain. Il had had middle-ear suppuration on the loft skie for sixteen years. Various mental tests with penell, watch, keys, et showed that he recognized the objects but could not name them, and a disgnosis was made of intracranial combination of a chronic middle-ear supportation.

The patient was removed to the hospital and a ridical masted doperation was performed and masses of cholesteatomatous material removed. Post led the way unward and backward, and a small opening of the skull above and behind the outernal ear canal exposed a fresh pinktab-colored pachymentogitis. The patient was of beseftled by the operation, and several days later an extensive opening when it is found to the small typer opening about 1 5 inches backward and about 5 to lines wide, exposing also the lateral sinus. Introduction of the

brain knife through the area of pachymeningitis to a depth of cm failed to reveal anything of importance. The patient did not improve

Four days later the dura which did not pulsate was incared vertically about half an inch behind the area of pachymeningits and a Jackson brain searcher introduced forward upward and inward liberating about sur drams of pus. There was no pulsation no colon bacilli were found.

Two days later the brain sear her was introduced backward liberating about three drams of pus There was no brain pulsation and not much improve

ment

Several days later the process was repeated the brain-searcher being introduced deeper and more forward over one oning of pus being liberated. The brain pulsated and the patient's condition was

improved

Three days later more pus was iberated. Pulsa ton was good. The brain searcher was directed to a point about 0 5 to 0 5 inch above the cychrow in the middle of the forehead and introduced to a depth of about 1 5 to 2 in hes. Wout one oun co from similing pus with gas was exacusted. A rubber drainage tube was introduced and there was a constant discharge. Firsh dressings were applied daily the rubber tube being reintroduced the length gradually being shortened for about five weeks when the brain wound had entirely healed.

The patient a par eption and recollection seemed to improve throughout the course of treatment When shown objects such as a nail hie collar button he could recognize them but was unable to name them readily. He could write better than he could read. He wrote rapidly but was unable to repeat

Cope V Z. The Pituitnry Fossa and the Surgical Methods of Approaching It La et Lond 9 6 cz 60

A pituitary body is present in all vertebrates but only in mammals is there a specialized protection afforded by the skeleton. In the human embryo

the fossa is formed at an early stage, a rece beam observable in an embryo of 25 mm. The current statement that the train pharvingeal, and lies between the present post sphenoid is in orrest. The canal traverses the anterior part of the post sphenoid. Radiograms of the eller fill hildren show that there is no particular age at which postal in trease in size occur.

The size of the primitary 15 is and later with its it immologiand it is an ome to perform the self-in

The fossa's surrund'd by a nun nhur mounted by an arrenal rile the rl 1 Wills. The venous circl is firmed by the run is and the antenor and postern rim ra mul 1 nuses. A pituitary growth as en hing trim the lossenters the arrenal mile pushing up the optic chiasma until the optic nerves are gradually strain gled between the no poli mand the article.

Abnormal tosse may be la ed enlarged reduced and deform i. Lularged sellae may be due to adenomatou ov rgrowth of the anterior part of the gland to mulignant neoplasm riginating in the forsa possibly to r peated phy jological enlargement due to in reased fun tional a tivity and more rarely to a general or local hydrocephalus chronic cir umscribed meningiti - r to tumors i other parts of the brain. Very mall forese are seen in cases of hypopituitarism, a sociated with im perfect development of the gland. The tossa may be deformed by tumors bur time from within or b interpeduncular neoplasms pressing down from above. In the former the nature, I the deformity would depend upon the rate of growth producing a thinning a cup-shaped outline or bani hment of all traces of the original shape. If the dorsum seller or auterior or posterior clinoid processes are obliter ated or markedly eroded there must be a large intracranial extension to the tumor

The pituitary fossa has been arrived at either directly through the ranium or indirectly through the facial skeleton the following table showing the routes which may be utilized

Temporal --

FACTAL

Name) -Septal resection (Schloffer, Hirsch West, Cushing, Kanavel, Halstead, etc.

Naml -Ethmold resection (Hirsch) Paranasal (Chiari, Kahler) Palatal (Koenig Preysing) Maxillary Suprahyoid pharyngotomy

Of these operations only four have been done in sufficiently large number of cases to merit special attention.

Horaley's temporal method is done in two stares. A temporal hone-flap is made in the first stage, and in the second, the dura is incised and the temporal lobe lifted up exposing the lateral aspect of the pitul-tary body. In Schloffer's method approach is gained to the nasal cavity either directly through the anterior nares or by reflecting the nose, or by sublablal incision. Varying portions of the sep-

tum and lateral walls of the nasal fossa are removed to furnish more room the sphenoidal sinus is opened and through it the pituitary fossa is approached. Hirsch and Cushing do a most ingenious subm cous septal approach. Cusling removing the vomer part of the median plate of the ethmold, and a strip of septum. The attachment of the septum to the sphenoid being exposed, the anterior and lower walls of the sinuses are chipped way and the floo of the exposed sells turcics removed. Hirsch removes the middle turbinates some days before the chief operation. The fronto-orbital method of Frazier is begun by forming an osteoplastic flap in the frontal region the roof of the orbit is removed as far back as the ootic foramen, the orbital contents are displaced downward and outward the frontal lobe is elevated and the dura incised for a sufficient length to expose the contents of the sella.

Other operations have rarely been performed.

The nasal route of Schloffer is fundamentally un sound, as are all of its modifications, excepting the submucous as the sells is approached through a region teeming with organisms or harboring foci of infection in adjacent sinuses. Considerable deformity of the external nose may follow also same objections hold against the palatal method which traverses the septic post-nasal space and also against the Chiari Kahler approach through the ethmold by external incision. Though Kahler has had some success with it it is too early to say much in its favor The temporal method has been found practicall by one operator only but with a

considerable mortality

The only justifiable method of approach through the sphenoidal sinuses is that of Cushing or Hirsch, especially that of Cushing. Of 3s operati as per formed by the sublablal method by the latter operator but one death occurred. With this method special skill in working i such confined space is ne

cessary as the surgeon cannot see what relationship his inserted spoon bears to the third ventricle. On several occasions it has been necessary t insert a metal clip for radiographic orientation purposes. A preliminary sounding of the sphenoidal sinuses is wise before undertaking this operation.

F cts in favor of the fronto-orbital method are that it provides an ascotic ro to, allows each step t be performed by the aid of sight and does not necessitate much dislocation of the brain as with the

temporal method.

The most commo indication for operation is oncoming blindness and it seems certain that in nearly all these cases there must be considerable intra cranial ext mu n. With the fronto-orbital method these enlarged glands present an easier object for attack Som cedema of the eye occurs after opera tio and sometimes the eveball may not be left quite on the same level as the opposite one. The latter drawback should be avoided by greater care it the time of operati n. The frontal sinus is sometimes in the way but by previous X ray or transillumina tion it can be voided.

While it is not possible to say which of the Hirsch fronto orbital methods is to be preferred, the autho believes that the latter is more suitable in the majority of cases.

E. K. Amorrowa.

RECK

W tson, L. F. Quinin and Urea Injections in Hyperthyroidism. V F M J. 916, cHi, 79

The author briefly reviews some of the methods of recent years that have been instituted with the sies. of controlling the hyperactivity of the thyroid gland. He emphasizes the necessity of rest, with proper ditetic and hygieni supervision as the foundation for any procedure in the treatment of hyperthyroidism and urges that the other ductless glands as well as the thyrold in each patient be studied their rol in contributing to the symptoms ascertained and treated accordingly

The author recommends outnine and ures infertions to relieve hyperthyroldism only and not to remove the goiter however small, recent goiters usually disappear following the treatment. M ch depends upon proper selection of cases. The technique is difficult and the method is suitable for use only in a hospital by men experienced in thyroid

surgery

The author describes an original method of raising the hyperthyroid patients threshold to stimuli by means of preliminary injections into the thyroid gland of a few minims of a sterile salt solution, followed by injections of sterile water given at one-When no hyperthyto three-day intervals. roldal reaction follows the water injections their usefulness is at an end. If these preliminary inections are omitted, acute attacks of hyperthyroid ism which might result disastrously are liable to follow. It is important that the slight pain of the injection be minimized by the use of local angesthe It is important that the patient does not come to dread the injections because the best results are secured through prolonged periods of treatment. E. H. Pool.

Marsh M. C. and Von Willer P. Thyrold Tumor in the Sea Bass (Serranus) J Ca cer Research OΛ 183.

The authors contribution to the pathology of enlargements of the thyroid in fish is based upon tive cases of thyroid enlargement observed in ser ranus (sea bass) The authors state that although thyroid tumors have long been known to occur in hish they have not been observed until recently outside the salmonoid group, and only rarely outside of domesticated hish where they are endemic and widespread

The only case known to have occurred in fish from marine waters besides the present specimens is the case described by Cameron and Vincent This was in a small shark of the genus squalus of the Pacine coast of North America.

The authors report that of the five tumors one specimen was plainly colloid goiter one was microscopically a step in advance toward epithelial increase of large alveolar type and shrinkage of the colloid content. In another the epithelial outgrowth was predominant over the colloid the cells having brome high columnar and the growth having taken on a definite adenomatous structure. In one case marked regression was indicated.

The growth in these specimens of serranus is not regarded as giving pronounced evidence of malignancy Little infiltration is exhibited through out the growth as a whole. In this respect the growths do not approach the process as exemplified in the fresh water salmonoids or in the case of squalus. The bodies of the fish were not examined for metastases The authors believe the tumors to be true neoplasms representing early stages of processes which are of essentially the same nature as the other thyroid overgrowths in hish which have been the subject of investigation

The authors call attention to the fact that iodine acting through the water medium even in great dilution has a marked action upon thyroid hyper plana or more advanced overgrowth in fresh water fish, reducing the heightened epithelium restoring colloid and effecting regressive changes in They claim that their specimens are of general additional importance from the fact that the fish were removed from the sea to an aquarium supplied with sea water and were habitually fed with marine fish chiefly the pilchard (clupes pilchardus) They received no mammalian tissues. They acquired the growths in sea water which contains a far greater concentration of rodine than that which is effective in reducing thyroid hyperplasia in fresh water fish

Gaylord H R.: Further Observations on So-called Carcinoma of the Thyroid in Fish J C a cr R arck 1010 107

The author reviews the literature of the so-called carcinoma of the thyroid in the salmon ids

The disease was first described by Bonnet in Although this author did not recognize its nature, Scott in 1591 regarded it as cancer and Plehn in 1002 recognized it as a neoplasm of the thyroid gland. In the same year it was discribed by Gilruth as epithelioma affecting the branchial arches A comprehensive histological study based on some ten specimens of fish was made by Inck in 1905 The author a contributions to this subject date from 1008 with the description of conditions existing in a hatchery in which hundreds of fish were affected The disease has been studied also by Marine and Lenhart beginning in 1300 and they consider it to be endemic goiter Gaylord's atulies were published in monograph form in 1914 and led to the conclusions regarding the nature distribution and significance of the disease which are summarized in this article Gaylord emphasizes the fact that the disease is endemic in a ery high percentage of all trout hatchenes in the United Stat's that the occurrence of the disease in mild fish its production in hish cultural stations its localization in certain troughs of water supplies the method of its spread its transmission to mammals the efficacy of three well known inorganic germicides in the treat ment of the disease the destruction of the agent by bolling and the phenomena of spontaneous recovery and immunity strongly indicate that the agent causing the disease is a living organism

Gaylord states that as there is no line of demar cation between what is called endemic gotter and what may be considered as cancer of the thyroid endemic golter and carcinoma of the thyroid in the salmonoid are identical

The cases found in sea bass by Marsh and von Willer the thyroid tumor found in squalus or small shark by Cameron and Vincent together with the evidence which has been collected regarding the existence of thyroid carcinoma in his living under natural conditions, and hence unaffected by over feeding overcrowding etc. strengthen the conclu sion that the disease is not the result of artificial propagation. The occurrence of the disease in sea hish bears rather strongly upon that theory of thy rold hyperplasia which attributes it to a deficiency of sodine in the food or environment. In fact so far as fish are concerned the similar results obtained with mercury and arsenic would seem to show conclusively that rodine acts in a manner similar to the metals, and not by supplying a denciency of iodine in the gland

The observation that mercury, arsenic, and iodine when introduced even in small amounts into the water containing fish with thyroid tumors bring about a marked diminution in the size of the neoplasm, develops increased significance in the light of recent experiments reported by McCarrison.

In discussing the question whether the foline acted as a purifier of the water especially as ger mixide or whether its effect was to be attributed to its supposed physiological influence upon the thyroid gland, McCarrison tated that he had obtained equally if vorable results in the treatment of gotter with thyroid hence he was not inclined to attribute to kolline a distinctly physiological action in the treatment of gotter

McCartion's experiments do not show condinitely that th iodine worked by destroying an agent in the water supply for the possibility till remains that it may have exerted some germiddial flect in the individual drinking he water. It is to be regretted, therefore that he did not entirely substitute chlorination of the water for treatment with

iodine

Littl E. G. Scierodermia Associated with Graves Disease, and Later Myzoderms, Complexously Benefited by Implantation of Human Thyroid into the Bone-Marrow Proc Rev Sec Med 9 6 to Dermilel Sed 59

The case is described of a lady aged 52 who in po presented the symptoms of Garara disease to a mild attent. In 908 the developed myracels—attent point in 1008 the developed myracels—attent point in 1000 indicated marked amenia, well as points in the shoulder and neck bathered between much that the shoulder and neck bothered between the shoulder and neck bothered between the shoulder and neck bothered between the shoulder and neck bothered between the shoulder and neck bothered between the shoulder and neck bothered between the shoulder and neck bothered chair strength of the shoulder and the s

Implantatio of thyroid was mad int the tibia in 1011 Following this the sciencemia was much improved. She was taking sodothyrine t this time. In 9 a secoal implantation of thyroid tissue was made. In 9.3 pyornbox alveolarms was diagnosed. After having all her teeth removed, there followed a remarkable change in her general health and appearance an improvement which has been steadily maintained. At present the fingers have become feetible enough t permit her to play the piano. The ski of the face is suppl and otherwise normal. H G Stark.

Gronnerud, P The Technique f the Enucleation Thyroldectomy Illiant II J q 6 xxix 50

This operati will be found practically pplicable at all parentymatons getters, whether of the crutic, colleds, fibrous, or mixed variety but should never be attempted under the vascular or active hyper plastic enlargements. It is a method very largely eliminating the use of clamps and accompanied by miniman loss of blood, never followed by never complications and when even medicore surjical

judgment is available, of extreme breadth in application.

The usual low skin incision is made. The fascus is raised slightly and cut parallel to the contained veins and the deavage line between the revealed edges of the stemothyroid and sternohyoid muscles observed. These muscles are separated and retracted, revealing the encapsulating fascia of the gland. It will thereupon appear that the true capsule of this organ blends with the so-called Kocher fascia and is very rich in arteries and veins. When the auterior fascia, which is comparatively free from large vessels, is opened the thyroid capsule will be seen. No clamps re used in these procedures, hemorrhage so far being slight and automatically ceasing in the correct separation of the timue layers. The true capsule is then opened int and, by posterior pressure, the tumor delivered The tumor may be enucleated without difficulty leaving comparatively bloodless bed which de picts the arrangement of vessels in the true capsule.

In 98 thyrodectomies in which the above technique was followed the application of champs to the inferior thyrodi attery was eccessary in two cases, but being inside the capsule no injury to the nerve was possible necessity for champing the superior thyrodi artery did not rise. Down I. Company.

Paterson, W J bling J W and Eggstein, A. A. Serum Changes Following Thyroparathy roldectomy J Exp Med 9 6 vm, 409.

The experiments here recorded were made on dogs. Thyroparathyroidectomy was performed in infreen animals, and the scrum changes were st died. The following two experiments were typical of the relations noted.

On the first dog weighing 5 kHos complet thyroparathyroidetomy was performed June 9 5 Tetany was observed on the third day following the operation on the fourth day the dog showed no symptoms but on the next day (June 3) there was marked testany. The similar was I und dead the

following m raing

On the second dog weighing 8 kilos complete

thyroparathyroidectomy was performed June 8, 915. Tetany was noted on the alternoon of June oth again on the following afternoon, and the next morning (June) when the animal was killed. In the first dog there was a gradual increase in the autorement sites until the time of death, with an

antiferment ther until the tim of death with an irregular protess curve. The maximum protesse scilly was oxed in the saimal during the tim when the tetany was most parent. The non-congulated nitrogen of the serum increased to more than twice the original amount. The lipses remained constantly low. The proteoses increased markedly. The smino-nitrogen of the serum in this animal showed no change except an initial decrease.

In the second experiment the conditions were different. The antiferment ther showed marked ill ctuation the first decline appearing shortly after the operation. The protesse remained low until the last day but the non-congulable nitrogen increased as in the previous animal the proteoses also accumulated during the period of tetany The increase in amino-acids was similar to that observed in practically all the other animals during tetany. This was the only animal of the entire series in which a rise in the linase titer was observed.

From their study the authors draw the following

In thyronarathyroidectomized dogs the on

set of tetany bore no constant relation to the ter ment antiferment balance of the scrum

2 The serum lipase titer r m ined it a low level

throughout 3. A progressive in rease in n n ougulabl mitrogen and proteoses was beerved in the scrum follow ing the removal of the gland

A The amino-nitrogen of the crum was usually increased at the time when t tiny wi mixt marked. (I R R E BEILBY

SURGERY OF THE CHUST

CHEST WALL AND BREAST

Menzies, J. L.: Notes on a Series of Seventy five Gunahot Wounds of the Chest Brit J Surg 0 6 111 66

The statistics of a series of 75 cases of guinshot woun is of the chest are reported by the author. and 12 of the more interesting cases are described in d tail

The most notable feature of the series is the rapid recovery where there was no destruction of the heat wall as compared to the high mortality in cases with open wounds. Where the pleural cavity communicated with the outer air the results were almost uniformly fatal

The symptoms are pain shock dyspnces, and hamoptysis and are due to damaged lung tissue and the resulting escape of blood and air into the pleural cavity I am is always present but is rarely severe On the other hand shock is usually pronounced Dysprica is almost always present and is most severe immediately following the wound abating within twelve to twenty four hours

Hæmoptysis occurs in the majority of cases seldom however being severe and lasting only two or three days. In the series 2 had no bleeding in 40 it came on immediately after injury and in 8 it was delayed from one to twelve hours. In all cases there was a rise of temperature

In the base hospital dyspaces and pyrexis are the prominent symptoms depending on the presence of an effusion and whether it is steril or septic, the amount of effusion determining the degree of dy pnica. In the series effusion took place in 70 40 were sterile 10 showed slight infection and 11 marked infection.

I neumothoray was present in 14 of the cases in 8 it communicated with the outer air Surgical emphysems was present in 12 and required no treatment Twenty-seven cases were discharged as cured with the missile retained but causing no vinotoms

The ases were divided into those with wounds which were healing or healed and those with wounds opening into the pleural cavity at admission There were 6 cases in the first class and 8 in the second. Thee of the first class were much more

favorable for treatment 66 recover 1 n l r died of sensis. The majority i cillu ion logically sterile

In the second class there vis marked destruction of the chest wall all were infactal involvemorneu mothorax) and the mortality was a ry high Of 8 cases 7 died. Autopsi s show 1 xt nsive la era tion of the lung with lung at se sees a reading from the track of the bullet

In the entire sen s 6 r os r l and s died the deaths being due to sep is

In the treatment rest i parin unt morphia being used as nieded

When the effusion is fund to but it may or may not be removed depending upon the case. If left alone recovery is prolong 1

If the effusion is infected arly trainage is in dicated resection of a porti n of a rib with a large drainage tube giving the best results. With a large empyema cavity the prognosis is grave

Larly rising with general and breathing exercises was found most beneficial P. M. CRASS

Newbolt, G. P. Clinical Lecture on Cancer of the Breast Med Pess & C

In the author's opinion three reasons still militate against cancer of the breast (1) bad advice of the family physician (2) failure of the pati nts to re port the presente of the tumor (3) disinclination on the part of the patients to have the radical operation done. Another factor which influences the lasty to believe that the tumor is not cancer is the fact that it is not painful

The author lays stress on the fact that the nipple need not necessarily be retracted in cancer of the breast. He thinks that where the supraclavicular glands are involved the outlook is extremely grave, and the prospect for cure quite remote nosis usually depends upon the stage of the growth at which removal is undertaken as well as the age of The prognosis in young and healthy the patient persons is bad. The best results are in women over In males the outlook is extremely poo tention is called to the frequency with which metastasis occurs in the opposite breast sternum spine, II G SLOW and hip

Gatewood Tuberculosis of the Mammary Gland.

I terst 11 J 9 6 xxiii, 71.

The author credits Astley Cooper with having described the condition in 1839 Dubar in 88 first described the disease microscopically Deaver collected 94 cases which were reported between 194 and 95 and Durante collected 150 cases

Tuberculous f th b east has been classified into primary and seco dary groups the primary group compensing only those cases in which the disease was limited clinically t the breast and the disease was limited clinically t the breast and the disease was limited clinically t the breast and the disease was limited clinically t to be proposed mortem has been mad in which the condition was so localized Gatterwood is f the opinion that all cases of t berculous of the best are but

secondary manifestations of tuberrulous clawshers. In the majority of cases the bacillus reaches the breast through lymph channels, probably retrogate embolic pocess. The disease unsulty occurs in the female breast. No cases have been bestred before poberty cases musulty occursing between the ages of 3 and 50. The most frequent initial lesson as palaless tump in the breast. Any patient presenting lump in the breast and complaining of pain in the region of the tumb.

The progress of the disease is usually rapid. One breast is involved as a rule. The lymph-nodes are enlarged in from 60 to 70 per ent of the cases.

Fixtule retractio of the mpole, and enlarged implegiands on the affected side are the most coestant physical findings of the disease. The majority of the cases present turn in they may be discrete, disseminated, or become confluent. The comstatency varies with the amount of linguistation and casestion. The skin becomes adherent to the mass and summes a dark red appearance this is followed by a rupture, discharge of caseous material and sinus formati in

Tuberculosis of the breast must be differentiated from syphilis and actinomycosis Potassum iodicle is almost specific f both

The after-care is important The use of t berculin is a ungical.

The after-care is important The use of t berculin is of mentionable val e.

Robinson, S. Treatment of Chronic Non tuber culous Empyema. Surg Green & Obst. 9 6 xtll, 557

Three types of cases are mentioned () those with an operative drainage wound () those with leakage through a secentialit opening (3) those with broachild drainage. Several types of cavities are described and flustrated lateral cavities, amail and large, anterior cavities, posterior cavities, cavities in the upper thorat segment multiple cavities designated as generally fatal. A prehiminary drainage operation regardless of previous openings is imperative at least six weeks previous to any opening oversition for cavity obliteration. Openings is

obliteration should be without mortality. The Estlander Schede, Wilms Delorme-Fowler, and S d k methods all possess advantages and also sources of error.

Muscle implantation may be employed in cavilies of moderate size utilizing the latistimus dord muscle dissected from the Schede U-shaped flap. The operation is preferable to those requiring partial resection of the scapila, described by Sudek and thers, the latter prod cing limitation of shoulder m tion.

Another operation is described involving the infolding of lateral skin and muscle flans with exposure of the entire cavity for subsenent aking grafting or stim | tion f granulations and epithelial axation. Surgical success depends upon the choice single method or a combination of methods pplied with accurat knowledge of the extent and location of the cavity and with conservation in the umbe f operati e stages. The on-operative treatment of chronic empyema such as vaccine therapy and antiseptic inject ons, produce sympt mati relief and a diminution in the discharge but the rehef is more present than real. These treatments are frequently musapplied and generally serve unnecessarily t postpone obviously indicated survical therapy Bramuth and vasel ne injections (Beck past) re i dennite curative value in cavities primarily small or reduced to suitable dimen alons by perations.

Ewing, J. The Thymne and Its Tumore; Report of Three Cases of Thymoma. Serg. G; et. & Obst. 0 6 xth, 46

The thymus reticulum is composed of modified cpithelial cells, while the parenchyma cells are lymphocytes which have wandered into the stroma from without. The evidence indicating the derma toss of thymus parenchyma cells from the epithelial stroma is unsatisfactory.

General pathological conditions affecting the thymus incl de abermacy of thymus time in thy road sample byperplasis in status lymphaticus, craves disease, and simple lymphaticnoms, exfoliation of reticul in cells in lenkennis and infections cysis and neoplasms. Cysis since from fections cysis and neoplasms. Cysis since from the control of the control of the control of the six and ventral ectoderm, from distended softened Hassall corpusales and from lymphanicomatic.

Neoplasms include round-cell growths, commonly classed as lymphosarcoma and tumors composed of flat or cylindrical epthelium. There are rare myxosarcomata of congenital origin, but malignant tumors arising from the connective them probably d not occur.

The so-called round-cell tumors, properly called thymomata, are derived from the epithelia stroma cells, and may be distinguished from true lymphocytomata of lymph-odes. The cells are not round lymphocytes but polyhedral or cylindrical, or giant derivatives of the stroma cells. The same variations in structure are observed as in Hodglin a granuloma and reticulum-cell sarcoma of lymph-The clinical course of these tumors also varies from the character of a progressive granuloma to that of a highly malignant locally aggressive neoplasm which may produce widespread exten sions and metastases. A notable feature is per foration of the chest wall. The anatomical position and peculiar structure usually permits a satisfactory diagnosis. Thymic carrinoma includes those tumors composed of pavement, cubical or cylindrical epithelium, but there is no sharp dividing line between the two groups and both arise from the reticulum cells. The parallel existing between thy mic granuloms and thymoms on the one hand and lymphatic Hodgkin a disease and reticulum-cell sarcoms on the other suggests that in both organs an infectious agent initiates an infectious process which often runs into a neoplasm Most reported cases of the transformation of Hodgkin's disease into sarcoma relate to mediastinal and probably thymic tumors.

The reported cases include a rapidly progressive febrile case with very criteria versals on of the neck, chest and axillize by a tumor of diffuse structure a periorating sternal tumor of two years progress structurally resembling Hodgkun s granuloma, re-gressing under X-ray and a slowly progressive thytioma of granulomatous type. Ilimited to the mediatatinum and showing polyhedral reticulum cells

and Hassall a corpuscles.

TRACHEA AND LUNGS

Moore A B and Carman, R. D Radlographic Diagnosis of Metastatic Pulmonary Mailg nancy Am J Recutgenel 1916 ill 126

The authors give a report based on 71 positive cases examined at the Mayo Clinic by both clinical and radiographic methods

LOCATION OF PRIMARY FOCUS IN CASES SHOWING RADIOGRAPHIC EVIDENCE OF METASTASES IN THE LUNGS

	Y Cases
Total number tabulated	71
Breast	20

Lung	i
Abdominal and pelvic masses	4
Origin not determined	
е	4

Men Women Average age Average time since growth was noticed	32 39 45 5 years 2 25 years
Histologic examination Carcinomata Sarcomata	50 ases 40 cases 16 cases
Hypernephromata	3 04565
Enlargement of superficial glands Enlargement of deep glands	8 cases
Other foci of metastasis	[4 (.150)

Apparently no idea as to the presenc of pul monary metastasis can be gained from the extent of the primary growth. Many cases with extensive involvement showed no metastasis while in many the primary growth was small and death operable except for the radiologic evidence of metastasis.

Fourteen of these cases showed metastasis in organs other than the lungs or lymph nodes. The other organs most frequently involved were the

liver bones and brain

Of the patients operated on 42 had been subjected to surgical procedure for the removal of the primary growth of these 10 showed local recurrence. The average time from the operation to the discovery of the metastasis was 15 months.

Cough was present in 32 cases. It was usually dry hacking and unproductive expectoration hav fing been noted in but 8 cases. Only 4 gave any history of blood spitting. The so call d prune Juice sputtum, regarded by some observers as indicative of this condition was not observer.

Dyspnora occurred in 30 cases. It was usually progressive and, when marked tended to be spasmodic in character quite often simulating asthma

Pain referred to the thorax was not d in 14 in stances, usually described as gnawing and not in fluenced by respiration

There was both clinical and radiographic evidence of pleural effusion in 12 of the cases.

A very striking feature was the relative absence of definite physical findings.

The conclusions are

r Pulmonary metastatic malignancy is not an uncommon condition and may occur regardless of the seat of primary focus.

2 Pulmonary metastasis bears no relationship to the extent or duration of the primary focus.

3 The clinical picture in a majority of these cases is very indefinite neither the subjective nor the objective manifestations being characteristic.

4 Metastatic pulmonary malignancy is a definite roentgenographic entity appearing in the roentgenogram as clear-cut circumscribed areas of increased density.

5 In many instances the diagnosis can be established only by the rountgenogram. By routine roentgenographic examination of the thorax many patients suffering from malignancy will be saved from useless and unwarranted surgery.

DAVID R BOWEN

PHARYNY AND GESOPHAGUS

Hirsch I S. Th Roentgen Ray Study of the (Esophagus, Interst. If J 0 6 xxill, 42

Hursch's paper is comprehensive. For a contrast mixture he uses a tablespoonful of bism the bear bonat (subnitrat) stirred for about ten min tes with a teaspoonful of m cllage of acada. The resulting mass is viscous and by conting the walls of the resonbarus outlines it lumen. The vamination is essentially fluoroscopic b t plates are also made The obliq e view either d moventral or ventrod real, is imphasized. Two periods in the act of s allo ing the buccopharyngeal and the cesopha-geal, may be differentiated. The bolus is propelled by the pharyn into the resophagus with great force and apidity It is carried through the ossophagus by peristalus Solid food is carried down solely by peristalais, while liquids are jected from the pharyingo emophageal junction (int oltus) to the cardia. The wave is deepest in the lower assophagus where t is necessary t vercome the sphincten ction at the cardia.

Foreign bodies are most frequently impacted at four points opposite the cricoid cart lage above the arch f the aorta at the crossing of the left bronchus

and at the disphragm

547

Two great classes of spasm may be differentiated the primary so-called idopathic spasm, the etiology of which is not clearly understood and the second ry spasm, the reflex of irritation inflammation or lceration. The former affects the lower end of

the gullet and leads to dilatation the secondary spann may involve any part of the lumen Spann is indicated by the arrest of the bism th in con shaped shadow t the constricted point. In the primary cases with dilatation there may be rapid deep peristaltic waves moving to the base with occasional regurgitation. The outline is smooth and symmetrical above the point of obstruction.

Benign or scar stenosas is usually asymmetrically situated, while the extent of the stenotic area is short Stenosis due t corrosives is most frequently found either at the pharyngeal mouth or in the upper

dorsal part of the tube.

The commonest form of stenosis is that due to carcinoma. At least 70 per cent of patients complaining f dysphagia have this disease of the gullet. As a rul these tumors involve but a part of the surface of the tube rarely de they involve its en tire dreumference. This acc unt for the irregular asymmetrical filling defect. Dilatation above it is never marked Peristalsis is absent over the in vaded area and distal to t

plicity of the lesions.

Diverticula are of two varieties, pulsion and trac tion. The former are most common are situated high, car the introtus and ppear as pouch-lik djuncts to the ersophageal I men

ATREET MELTE

Moore, I The Removal of Foreign Bodies from the Esophagus and Bronchl; with a Description ! Some New Instruments. Land, Lond., 0 6 64 90

The author has designed a new non-slipping for ceps f removing foreign bodies of any description. The blades are shaped on the principl of crab claw the pper blade being curved and having at its extremity a triangle tooth which fits between two similar ones in the lower blade. Both blades are transversely serrated giving greater security t their hold on a foreign body. They are in addition grooved down the center so as to prevent any lateral allpoing. He has also devised an endoscopic cutting forcers or shears which combines both the grasping action of forceps and the cutting ction of shears.

Orro M Rorr

SURGERY OF THE ABDOMEN

ARDOMINAL WALL AND PERITOREUM Sampson, H. H. Clinical Notes on Penetrating

Wounds of th Abdomen Bru II J 06 L

The extent of the visceral i jury caused by rifle large extent on bullet in the abdomen depends t the distanc the bullet has traveled before the impact. The most extensive wounds are caused when the range is less than five hundred yards.

The importance of primary hemorrhage lies in the f ct that there is little tendency toward apon taneous arrest. When seen three or four hours after the receipt f the injury small arteries in th wounded bowel are still sourting visorously. In fatal cases death is almost invariably d e to pri many hiemorrhage. It becomes obvious, therefore

that on this account alo e, every effort should be made to convey the abdominal wounds with the least possible delay t place which is equipped for operative treatment

One case is reported in which a bullet traversed th peritoneal cavity in an area occupied by intestines without causing perforation of the viscera with which

t must have come in contact.

Nounds of the small intestin are generally multiple but are usually confined to one segment of the bowel. Wounds of the colon are often com plicated by injuries to other viscers. These cases show a high mortality. If h wever the injury is confined t the colon, the outlook is more hopeful. provided operation is performed before a widespread peritoneal infection has occurred.

Wounds of the stomach bleed freely but if un compleated respond well to operative treatment Wounds of the liver give the best results. In simple perforations hemorrhage is slight bile drains away for a few days recovery is the rule

The spleen is seldom injured alone. Its injury is often associated with that of the left kidney pleura and lung.

J. H. Skiller

Fraser J and Bates, H T Penetrating Wounds of the Abdomen B t M J 0 6 500

The authors report the operative results in penetrating wounds of the abdomen and discuss their observations in these cases

In wounds of the atomach the degree of damage depends on the nature of the projectile and the part of the stomach injured. Shell fragments produce the most extensive destruction while bullets generally behave as in other soft tissues i.e. small entrance wound and larger exit wound. Bullet wounds of the center of the stomach produce the least destruction those of the pylorus quite extensive laceration while those of the greater or lesser curvatures are accompanied by widespread splitting and tearing of the tissues. Hamorrhage is not severe unless one of the larger vessels is ruptured.

Clincally this class of cases shows pain, sick ness collapse abdominal rigidity and tenderness the sickness being more pronounced than is usual and the collapse less marked. The pulse and respiration rates are increased the latter proportionately more regardly than the former Pain is more pronounced when the pilone or cardiac ends are involved and collapse more marked in wounds of the curvatures.

In the operative treatment the authors employ a left rectus incision, occasionally enlarging it lat erally. When the situation of the wound is doubt ful an incision parallel to the left costal margin is used. After rigid inspection one of three lines of treatment is instituted (i) simple suture (2) gastro-enterostomy or (3) pylorectiony with partial resection depending on the conditions found.

Six illustrative cases are described, 3 of which died 2 recovered and one was unoperated. Suture was used in 3 cases gastro-enterostomy in one, and resection in one

Bomb fragments wounding the small intestine cause small inultiple wounds with invaginated edges and a marked tendency to surrounding harm orthage. Bullets traveling at high velocity cause small equally sized perforations at low velocity, they cause considerable destruction of tissue. Wounds by shell fragments are usually quite extensive. Wounds of the free edge of the gut involve more tissue destruction than those of the fixed or mesenteric border.

Bleeding from the small intestine is usually severe especially in the jejunum and mesenteric hæm o rhage is always progressive. It was also observed that the less the damage to the gut the

more likelihood there was of extensive peritoneal soiling. Massive injuries inhibit peristalsis

Bullet wounds of the buttocks it as noted are liable to be tollowed by evidences of injury to abdominal viscera

Clinically these cases show ign of beginning peritorities coupled with those of hæmorrhage the symptoms of bleeding coming on mit if flowed by those of peritorities. The abd min linguisty when bleeding is profuse free disappear.

The author advantes the milline in ison and a omplete inspection of the nur mall gut before deciding upon the best method of procedure. The various methods are 11 staple uture () resection followed by lateral r nd to-end anast mosts (3) resection at leting rary enterostomy.

With sample suture it was found essential that the wound be mall dest undamped and mesen tery intact. Wounds b b mb fragments are ideal for suture. The wound edges ere not excised and linen thread was used.

The indications for tee tion and anast mosts are numerous perforation tenule size and degree of injunes and involuming or related mesentery. This procedur is highly factored by the authors. They also predy the factor anasteromosts as being less likely to be a llowed by paresis and distention of the provintal segment.

Resection and ent rost my are only indicated as an emergency measure in rapidly de eloping collapse during operation

A synopsis is given of 21 illustrative cases 1 dled recovered and were unoperated Suture was done in 5 resection in 13 and enterostomy in one

In wounds of the colon the effects of the different projectiles are similar to those in the small gut with the exception that the septi-material is much more likely to be walled off by adhesions. Pentonitis from such wounds however is intensely virulent.

Clinically the symptoms are likewise similar to those of wounds of the small intestine except in not being so widespread and with an absence of early sickness or nauses

In the treatment if the case comes to hand later than twenty four hours enlargement of the onginal wound and drainage is the best plan on the possibility, that the infection is becoming localized caller it is west to open the abdomen through a separate incusion. The methods best adapted to this class of wounds are simple suture with colotomy resection not being deemed advisable. Drainage of the retrocolic space is always recommended.

A synopsis of 12 illustrative cases is given 7 died and 5 recovered.

In wounds of the spleen the presence of free fluid in the abdomen evidences of hamorrhage and the exit and entrance wounds diagnose the condition

Splenectomy is usually indicated.

Two cases are reported with one death and one recovery Wounds of the liver gall bladder and docts are

usually complicated by damage to the overlying lung or pleura. It is not usual to have m ch destruction or disruption I tissue in wounds of the liver and nost traumatic laundice is uncommon.

The clinical symptoms may be remarkably absent, the lung symptoms frequently disguising the shiominal condition. Abdominal guidity increase of pulse, and temperature and pain over the liver are observed.

Cases showing progressive hamorrhage or com-

plications of other viscera only were operated

A synopsis is given of 14 cases all of which recovered.

In kidney wounds, extensive organic disintegration may occur with merely slight wounds. Hermaturia may or may not occur in severe injury the kidney pelvis is usually blocked by a blood-ctor.

Treatment consists in (1) simple drainage () Lidney suture, and (3) nephrectomy

Three cases are reported, all of which recovered, simple dramage being used in two and nephrec tomy in one.

In wounds of the bladder it was observed that intraperlioneal wounds are untually complicated by injuries to the rectum and small bowel, and that a non-penetrating wound of the abdominal win may cause rupture of a full bladder. Clinically the symptoms were the usual ones of bladder injury Drainage, superpublic, uretural, perincal, was indicated. Four cases are reported with one recovery and three deaths.

In wounds of the rectum the entrance wound in smally in the bottocks and, as a rule, fracture of the pelvis and injuries to the small bowel compilicate the case. Hemorriage is profuse, and appears from the rectum as well as internally. The treat ment is that of the compilications. Two cases are reported with two deaths.

The conclusions are as follows

1 In the majority of penetrating abdominal wounds operation offers the best chance of success. Spontaneous recovery rarely occurs.

It is advisable to walt one or two hours for symptoms of shock to abote unless evidences of progressive hemorrhage are found. Warmth and 1 ccm. of pituitary extract are used.

3 Three to four pints of saline administered subcutaneously during operation and closed other anisothesis are to be recommended.

 Careful abdominal inspection and examination before instituting treatment is advisable.

 In early cases of extensive peritoneal soiling the abdominal cavity is t be washed out. After peritonitis has set in, drainage only should be used.

peritonitis has set in, drainage only should be used.
6 Speed and every possible avoidance of shock are important factors.

 Post-operative rectal saline and subcutaneous infusions are to be recommended.

8 The prognosis depends on the degree of injury

and the time elapsing before treatment is instituted.

Early operation offers the best and surest chance of ultimate success.

P M Chase.

Abadie, J. The Treatment of Penetrating Wounds of the Abdomen (A propos of traitement des philes penetrantes d'abdomes) Bull. et suin. Sec. de chir Par. o 6 phil 250.

The other reports on two series of observations those treated by laparet my and those which recovered in spite of non interference and in which the proof of penetration had been made either by N ray or by visible lemons.

Lapatotomy was perf rmed on 5 cases in 9 months including cases tangential t the peritoeum univisceral intentinal perforation, inceration
of the liver inceration and perforation of the intestines perforation of the rectum bladder and
mail! I testine all these cases recovered. The cases
upon which a laparotomy was performed and the
individual succumbed included multiple sectioning
of the small intentine rupture of the urethra, per
foration of the colon, crushing of the eceum, per
foration of the bladder.

It is generally admitted that wounds made by bullets are less grave than those inflicted by fragments ! Howitzer shells. However the proportion of cases wounded by one or the other mean, depends pon where and how the fighting is carried on. The method of fighting in trenches dosely stuated explains the ranty of bullet wounds, and those occurring are extremely severe due to the short data or. The utbor has never seen a case I'a wound of the butbor, with belominal penetra tion recover without actual interference: the peritodist reveals the seriousness of small ornine f an anodic appearance. The presence of perforsitions or lacerations of the vestical aggravates the prognosis considerably. One of the author' cases on whom he operated recovered three died.

Whether or not to operat at open in shock or t postnone the operation is a question of considerable importance. Frequently the wounded have to be carried for a distance of Lil meters, and as the shock reveals two essential causes, severe hermor thare or nervous shock, the selection of treatment is momentous. A hemorrhage that has allowed a patient t be carried a kilometers could be modified momentarily in its ffects by injections with scrum and adrenalin the pervous shock can assuredly be lessened by tonics. The method pursued by the author consists in immediat injectio with cam phorated oil, ether morphine, if the wounded suffers intensely bundant injections with serum and mg. of adrenalin if intravenous injection is indicated it should be given liberally The injection with serum is continued even during the operation if it is indicated by the patient a pulse. In the majority of cases the author has poured on to 150 ccm. of ether int the abdominal cavity notably the pelvic the anse are cleaned by means of compresses in

bibed with warm serum in two cases he has re placed the ether by salt solution. Pelvic drainage has been practiced in all cases but one sometimes a second drain is inserted toward the lesions. For lateral and terminal anastomoses the author praises the efficiency of the coupled forceps of Temoin

Post-operative care consists in absolute diet Fowler's solution by the drop method rectally A maximum absorption of 4 to 5 liters a day is

considered sufficient

The author recommends the establishment of surgical stations near the front systematic arrangement in the immobilization of surgical ambulances for a small pace especially for laparotomies during highting specialization of a unit for that purpose where the number of units is sufficient if not sending a reinforcing unit with assistants and all the material necessary for efficient treatment.

The author believes that the treatment of choice for penetrating abdominal wounds in war as well as peace is laparotomy RAOUL L VIORAN

Lancer T F The Acute Surgical Abdomen Med R 0 6 122/2 648

The author s paper is based on a recent series of unselected acute abdominal cases operated on by him at the St Laurence Hospital New York most of them desperately ill such as one hands coming into an emergency service by ambulance. He makes a special plea for the early recognition and prompt operative procedure in this class of cases.

prompt operative procedure in this class of cases.

The following is a classification of this series of so scute abdominal lesions.

In troup A in 19 cases or 63.3 per cent of the total the appendix was the offender Of these cases 8 had had one or more previous attacks. In 6 cases the nullammatory proces had not extended beyond the walls of the appendix that is they were operated upon early. In 0 cases of appendicitis the damage had extended beyond its orgin, causing a local pertionnts with limiting adhesions. In 3 cases diffuse peritonitis had resulted from delay in submitting to operative interference. Of these 10 cases of appendicitis only 6 were seen early that is before the infection had extended beyond the appendix

In Group B in 5 of the total cases the uterine

adnexic were at fault

In G oup C in 3 cases the bilinry passages were the site of the lesion

In Croup D there were 3 acute operative cases a case of abscess between the layers of the mean tery of the small intestine a subdaphragmatic abscess of the left side traumatic in origin and a case of diffuse peritonitis thirty hours after perforation of a duodenal uleer

The leucocyte count proved valuable especially in cases with little or no ele ution of temperature low pulse rate and slight abdominal signs as in many of these cases the increased total count or preponderan of polym phonouclear cells in the

differential count was the only evidence of the seriousness of the lesson

Abdominal muscular rigidity pain and tenderness and a blood picture that shows a high total white cell count and a high percentage of pel morphonu clear cells in the differential ount reciber one constitute the exsential trial for dimanding operative exploration of the abdomen. The only exception would be in a case where the surgeon was sure that these signs were luston accute sal pingo-oophonits which should be treated conservatively at the beginning EDWARD I. CORNELL.

Crispin E. L.: Visceral Criscs in Angioneurotic (Edema St P | I M J 10 0 m

A large number of patients suffering from visceral crises particularly of the erythemic purpune, angion protic group are advised to undergo surgical operations

The author calls attention to this group of cases and discusses the diagnostic importance of visceral crises more from the standpoint of value in negativing or avoiding surgers who have not give relief than from the standpoint of too closely differentiating interfacted medical conditions.

Severe abdominal pain which to not conform to the true surgical types must be ontused with visceral crises for which surgers would be of no henceti

benen

When a history of severe abdomin it pain is given which does not conform to true surgical types care ful inquiry should be made as to the presence at any time of urticarias ervihemas jurpuras and swellings of angion wrotic adem it types.

A history of recurrent severe al dominal pains with constancy in the nature and duration of the attacks with skin manifestation of any of the exudutive crythenic forms with or without notice able association with the abdominal pains should excite auspicion as to the presence of crises of angionemoric type

À diagnosis of viae ral crises of angioneurotic type should not be made until careful examination has excluded or made independent surgical causes. In this roentgenologi examination of the gastrointestinal tract is valuable negative evidence. Syphilis and tuberculosis should be excluded.

The constancy in the recurring atta is of pain not conforming to surgical types in patients who have had skin manifestations of the evudative erythema group and whose general condition does not account for the suffering they have had to bear will warrant a diagnosis of visceral angioneurotic edema.

Repeated or even single attacks of int at nal cole, with tumefaction in which the patient sign rad condition is too good for the extent and se entry of the trouble and in which history of swellings can be obtained may be of this type. To wait is good surgery. The rapid return to health is trongly suggestive of vaceral angloneurosis.

Having determined the medical nature of these

gioneurotte viaceral crises even in these cases of ingioneurott ordema or the nutre exudative erythema group, we should endeavor t work out the sources of toxemia. These may be foel of pus in the upper respiratory tract and sinuses, bacterial absorption, idioxynerasies to heat, cold, chemicals, parasites, carbodydrates, or proteins that are th

causes for anaphylasis.

Removing the causes for anaphylasis whether it be kilosyncrasy in one patient to lee cream—some constituent or the odd—banana in another alcohol in a third, r any anaphylactic base o source of corpenous or endogenous irritation or polson, may give the patient relief that th advused sourcer or corpenous or endogenous irritation or polson, may give the patient relief that th advused sourcery would not have eiven him.

EDWARD L C RMELL.

Makins, G. H. A Study of th. Symptome and Complications of Gunshot Wounds of the Solid Abdominal Viscers. Bril J. Surg. 9 6 in, 642.

The utbor reports his observations o a series of gunshot wounds of the solid abdominal viscers, these observations were made in a basis hospital and do not include the immediate results of the

In wounds of the liver expecially those made by builtet, in many cases no evidence of liver injury is detected except that afforded by the course of the massle, provided the blied ct or no large vessels are injured. Thirty-seven cases only are reported on the grounds that the liver wound was the chief element and as Illustrating the varying degree of gravity which lesions of this organ may assume

Two classes of wounds were observed () those of a rupture due to contusion and (s) simple per forations. The liver offering considerable resistance as it does, is frequently commitmed or ruptured. The most common course of the missile is transverse. Of the 37 citest, I were transverse. Also

the simple furrows often give rise to more trouble some and persistent hemorrhage than the perforating wounds.

Shell wounds are usually most extensive they frequently give rise to secondary harmorrhage, and almost invariably are seriously infected from the start. Under these circumstances it is the rule to have progressive necrosis and sloughing of a great part of the liver

The most common coexistent injury is pleural and lung involvement. In the 37 cases, 5 showed pleural injury. Next in frequency come injuries of the stomach. Wounds of the right kidney are not rare but have a very good prognosis.

The symptoms and signs may be entirely wanting or very slight. Of the 3r cases, 7 showed no physical signs of liver injury. However bleeding into the pertioned cavity is one of the most common results and may lead to a rapidly fatal issue at best it is one of the most troublesome complications and is not often seen at the base hospital. If in larry is on the inferior surface the blood will collect

in the lesser sad and if on the anterior surface t will eventually collect in the pelvis.

Secondary bleeding usually occurs about the tenth day and is alw ys associated with septic infecting in the series it occurred a times. It is accompanied by pain bid minal distention, rise of temperature and occleration and loss of pulso volume.

In of the cases j undic was observed being deepest in scrious septic infectio. Deep staining if the uring its rare. It is believed to be hemolytic

in origin

The most haracteristic sign is the escape of the bild from the wound Som form of bilary fatula was present i 5 ses if the senes Perustence depe do ministly on the size and degree of infection of th ound Of the 5.7 howed natula opening by N v i the pleura and all recovered I none mast the oblects in of the bill in the peritorical cavity.

noted and in e was the gall bludder perf rated. With an open infected shell wound temportance, suppuration is the rul but is of o great importance. The formation f secondary becases however is

grav matter I the 37 cases, 4 subphrence abscesses developed with deaths and recoveries. The post in term records show that of 5 deaths

The post in term records above that of a deaths of oper ent to secondary harmorrhage. The most prominent complication causing death was hermothous 7 cases which kidney wounds complicated the ill er in 15. Practically all the deaths may be said to be do to sepans as secondary harmorrhage is alw ys d to infection.

The treatment at the base hospital is purely expectant. If the misell is easily coessible it may be removed otherwise no fresh incision is made.

In wounds if the spleen, diagnosis is rarely mad on any grounds beyond the polition if the external wounds and the direction of the internal track. Left hemotherax is the most prominent complication, followed by renal in turn.

Spontaneous healing is to be expected with simple peri rati us and moderat lacerations of the spleen. Death from hemorrhag from this organ is not at all

common.

Injuries to the pancreas are just as difficult to diagnose as those of the spicen and are usually found at operation or topsy. Three cases f wounds of the pancreas are cited.

In injuries t the kidneys the simple perforations may often be regarded as negligible. Twenty seven cases are included under this head as showing the complications most frequently associated with injuries t the kidneys. In z of these cases the

wound f entry or exit was in the loin.

The most common complications outside of in juries of the bollow viscers are wounds of the liver

spleen, and pleura.

Among the signs and symptoms, hematum is the most prominent, although often absent. It is rarely severe or pensistent. In the series, only

soan and warm.

Apparently the proliferating epithelium encountered some antagonalite influence which was constantly breating it down. Complete only removal of the disease has mass may be followed becomplet removed for meaning the same may be followed becoming termoval of the Sex of the same constantly before recurrence take place.

Handley W.S. A Method of Tracting General Particultis with Obstruction; Its Application in Military Surgery Bru M J 9 6 h, 5 9

The author discusses those cases of general peritonitis in which the accepted modes of treatment have falled t avert or relieve paralytic obstruction of the bowels and cites a case successfully treated

al ng lines laid down in his articl.
In cases of general peritoritis where the picture is one of complet obstruction death is only a matter of hours. Inmediately preceding this stage however is one not described in textbooks, wherein, while obstruction is usually complete the public is dailyely good, the would in not offensive, and the soft above with allght respiratory movements. This is the last stage in which surgical interference may help.

may acip.

Fortunately general peritoditis is rarely universal. The infection no matter where its source, as a rule begins in the pelvis and gradually spreads present gravity having carried the septic material d winward. Thus there is quite a period in the disease in which the upper addomen, ie above the umbilicus, is

comparatively free from afection.

Likewise the presence of persistent active vomiting may be considered hopeful, in that it shows that the stomach and upper intestine still retain their contractile power sithough reversed. Hence,

Handley believes that surgical interference in the upper abdomen before general collapse, is advisable and should be considered. The interference should invol e only the stomach, jejunum and transverse

coton.

Jejunostomy falls it is believed because it cuts of the supply of fluid to the mucosa of the large instance. Handley howeve recommends a jejunocolost my t the transverse colo with excessions and pelvi dransage. This relieves the vomitting establishes an emergency intestinal canal which supplies the body with dean food and fluid on the constant of the necessary to overcoming the general infec

This procedure the author tates may be carried to tiquicity and easily and practically without shock. A case is cited in which after an operation for perive appendicitis with begann it perfonds to symptoms of intestinal batruction is pervened given a characteristic pacture of ascending perioditis with test had obstruction. A jeunocolostomy with a excession was with a consistency was then done with immediate

improvement and complete recovery

In closing H diey states, I hold no brief for
my conclusions and only ask that they shall be
tested.

Saliba, J Th Antiseptic Action of Ether in Peritoneal infections. J Am. II Ass 9 6, ivi. 205

Saliba t tes that be has introduced ether into the abdominal cavity as a routin measure in 248 hospital axes of peritoneal infection. The injection is made with syringe just before the last peritoneal ture is tiled.

He concludes as follow

Ether e perimentally and clinically has been proved to hav bactericidal ction.

In peritoncal infections it is and and bene-

ficial antiscuti

3 The dose of ether instillation into the peritoneal cavity is one ounce for child above four years

and three ounces for adult
4. Generally no untoward after-effects and complications foll water use.

5 Any possible toxic action of ether on the various body organs is very slight. A. Emmurano.

Finochietto R. Retro-Inguinal Hernias. Surg. Gynec. & Ohn 9 6, xvil, 554.

Retro-inguinal hernias (Corbellini, 1906) are the right hernias of the classics, the internal hernias of Tiliaux, the juxtafuniculaires of Villete.

They are called retro-inguinals because coming outsite, they push before them the posterior will of the inguinal ensal the transversalls fascia. They are found i 63 per cent of hernias, coming to operation. The pincipal alteration of the walls is an atrophy of the conjoined tendon and Hessert a triangle.

The hernial tumor is slightly attached to the cord, but its base is fixed, owing to its co timuity with the transversalis fascia, which in this place presents its fibers of re-enforcement strong but separated

Ac ording to the predominant element in the hermal tumor ie the peritoneal asc, the pre peritoneal fat or viscers the hermas are classified in the order of their frequency sarular 73 per cent lipomatous so per cent splanchme o per cent for the lipomatous variety o upying the under part of the base of the because there is found an ample cavity with salls form d by connective tissue, which is a prolongation of Bogros space. These three variety-sofretro-inguinal hermas are independent of each other they do it follow one another

Simmons, C. C The End Results in Seventy Consecutive Cases of Umbilical Hernia Operated upon at the Massachusetts General Hospital Bo ton M & S J 916 civrly 34

The length of time the cases were followed after operation was from one to four years. Cases with our recurrence at the ind of one year were considered cured sin c the records sh wed that all previous recurrences took place within one year from operation.

The operations reported were performed by 21 different surgeons. The three main types were (1) closure of the ring vertically with or without an overlapping of the aponeurosis (2) transverse closure of the ring without overlapping (3) transverse closure with overlapping of the aponeurosis—the Mayo operation. The author described his technique in the last method which he has used in 14 cases without recurrence.

Simmons divides the cases into three groups (1) children and small hernix in thin adults 15 cases to traced all cured by various types of operation (2) stout adults 45 cases one death directly attributable to the operation for herma a mortal ity of 2 4 per cent Six cases of strangulated herma. were included in this group. Of these 45 cases the herma recurred in 10 or 22 2 per cent. In 30 cases closed by the Mayo method 10 per ent recurred In 14 cases closed vertically with or without overlapping 42 8 per cent recurred. Local sepsis apparently played little part in the recurrent cases of 31 clean cases 6 recurred of 14 in which there was local sepsis 3 recurred. Of the recurrent cases 4 were sutured with chromic gut 2 with kan garoo tendon and 3 with non absorbable material

The recurrent cases are described in detail and the cases in each group carefully analyzed the follow

ing conclusions being reached

I Small umbilical herrine in thin adults and umbili al herrine in children may be cured by any operation which removes the sac and closes the defect in the abd minal wall

- 2 Cases of umbilical herma in stout adults are difficult to cure. The Mayo operation of transverse closure of the ring with an o erlap of the aponeurosis gives the best results.
- 3 In adults closure of the ring by any other meth od than the Mayo na general hospital is followed

by 46.4 per cent of recurrences Recurrence if it is to take place usually does so in less than one year

4. The suture material employed has no relation to the libility to recurrence

5 Skin sepsis is very likely to occur but apparently has no relation to recurrence

GASTRO-INTESTINAL TRACT

Gasbarrini A The Ionic Concentration of the Gastric Contents in Some Stomach Diseases (Sulla orn trasione di neouto gastrico in alcun malatti dell t ma o I ter t Bestr bests ** there or ** tr ** the state of the s

The author used Sorensen's lately introduced calorimetri method of estimating the ionic concentration of the gastric entents. This ionic concentration gives an index of the disassociation of hydrochlon acid ie of the amount of free hydrochlone acid in the stomach

The author submitted to this process the gastric liquids from 30 patients with various stomach diseases and from his results he is of the opinion that the calorimetric method is excellent for clinical diagnostic examinations

The method and technique are fully described, also a detailed tabular statement is given of the 36 cases examined — gastne ulcer dyspepsia etc—and the findings in each case — N A BRENVAN

Friedman J C. Time Relations of Gastric Pains, with Special Reference to Gastric Adhesions Am J M S 0 6 cli 35

Friedman reports a number of operat d cases of gastrn pain with special reference to the time of occurrence as a diagnostic help. He divides all gastric discomfort of the intragastric and perigastric regions into continuous and intermittent varieties. The continuous pains are most frequently due to carcinous to marked pyloric obstruction, and to penetrating ulcers with peritoneal involvement. The intermittent pains are divided into immediate early and late. The immediate are found frequent ly in pions neurous obstruction of the cardia and various other conditions.

The early pains in luding those occurring fifteen to sixty minutes after eating are most often due to adhesions in any part of the stomach including ventral hernias and pericholecystitus

Late pains include those occurring one to three hours after eating and indicate an increase in intra gastric pressure or pylorospasm of which the most frequent cause is hyperacidity. J. W. Turbuza

Barbacci O Gastric Volvulus in Hour Glass Stomach of Congenitud Malformation 369 of Rotation (V viue gastri in tracco pe malf rmazione co genitar—360 di tadone) Rf $m \neq d$ 0 0 vixul 4

Volvulus of the stomach is undoubtedly a rare affection and there are only 30 observations of it

on record. In recent years it has been seen more frequently than in the past owing to the greater number of surgical interventions. The affection occurring in a so-called hour-glass stomach where the rotation is in only one gastric segment is still rarer There are only observations f this kind It is exceptional fo the rotation t exceed So Only a cases have previously been recorded in which the rotation reached the limit of ago The anthor now adds fourth to these a cases. The clinical history of the case is wanting. The nationt reached the hospital in a moribund condition and died short ly after his entrance. The particulars were gleaned from the autorsy On opening the abdomen there was found in the left precordial region a sac the size of a child a heard of semi-ovoid shape, the base being above and the apex below It reached to the level of the iliac crest, at which point it was twisted non its axis and evolved into another annarently smaller sac of semilunar shape, which occupied all the right hypographic region and had a general direction from left to right. On the left of this sac

were two greatly distended loons of intestine th pper corresponding to the descending colon and the lower to the sigmoid colon which was buried in th lower pelvis. On the right side of the sac was another distended loop which corresponded to the ascending colon. The viscerie generally were mal-

formed and displaced.

The l wer of the two sacs referred t has under cone a torsion on its axis. This torsi n amounts to 160 so that the anterior face of the sac which is presented to view is really the visceral anterior i ce after complet twist. This torse is ventied by complete removal of the sac and its attach ments

From the detailed andings the anatomic diagnosis was gastric volvulus in bilocular stomach with 160 of rotati abnormal mobility f the pylorus and duodenum congenital malformation of th eastrobenati heament, slight polmonary emphyse ma with hypostasis and ordema degeneration of the myocardia and live hepatic calculus i diplent nd renal arteriosclerosis etc. sorti splenic Histologic examination showed no alteration what ever in the stomach walls in either sa

thor thinks the two co diti as in this case whi h merit special trention are the bilocular conformation of the stomach and the gastric volvulus. Bilocular atomach is not rare. It may be congenitel or acquired although many authorities deny the existence f consental variety

The author is co vanced that in his case the de formity was congenital and gives his reasons discussing th theories of other writers, Barnabo Verrassat, B edlinger W listeln, etc who have devoted considerable ttentio to the occurrence of this congenital anomaly \eyramet has laid d wn the dictum that in order t be considered congenital th following should be fulfilled The billoculation should not cause any matric

disturbance during life.

It should of disappear under the influence of insuffiction of the stomach

1 It hould not be accompanied by any appre

ciable lesso of the gastric tunica

Biloculation is as likely t be met with in the fortus and I the infant as in the adult and the old In the a the s case the second and third condi toons wer fully met. The first ditions could not he established owing to the lack of sufficient history of the case

The author next takes up detail the considera tion of volvulus occurring in connection with bilocular stomach. From review of the literature of the subject he reduces such cases (nly Hegives a short résumé of these o cases. Only in the s cases reported by Hedlung Sch el and Walther, and Kocker did the rotation reach the limit of 360° as in the th r' case and that f Schu le and Walther was the only e in which the ther concomitants agreed with those of the case now reported The thor case is therefore nigu

II A BREYYA

Burge, W L. and Burge, E L. Th Cause of Gastric Ulcer J 4m 1/ 1 0 6 lxv1, 998

ecordance ith the theory that gastri alcer is caused by deer used resistance in the limited areas of the eastric wall the nibors undertook this in vestigati to determi experimentally if possible whether or of such diminished resistance would give ruse to gastri ulcer. They point it what has been known for some time that the resistance to the action of the digestive forces of limited portions of the m cost of the st much is decreased by cutting off the blood supply t these portions as, frex mple, by a cl t in small blood vessel (thrombosis) or by the ligation of the vessel and that under such conditions the area is directed by the pensin with the formation of an ulcer. The fact that matric ulcer occurs so frequently in anzenic persons led t the advancement of the theory that the oxidative processes are decreased and that this may be the cause of the diminished resistance of the times.

Working upo the theory which assumes that simally balance exists between the oxidative processes of the cells f the m cosa and the digestive action of the pepsun in the stomach, and that if this balance is destroyed, as for example by depriving a limited area of oxygen by cutting off the blood supply and thereby decreasing the vidative processes of the area this area should be directed by the pensin with the producti n of ulcer the authors devised numerous experiments t imitate the protective mechanism as thus set forth From their experiments they are able t draw the follow ing conclusions

The decreased resistance of a circumscribed area of the tomach to the digestive ction of gastric julce is due to a decrease in the oxidative processes of the cells of the area. Gastric ulcer is due to the subsequent direction of the area by pensin.

The resistance of unicellular organisms (para.

meciums) to the digestive action of the proteolytic enzymes can be increased or decreased by increasing or decreasing the intensity of the oxidative processes of the organisms the greater the intensity of the oxidative processes the greater the resistance and vice versa. Groom E Britay

Elliott T R. and Henry H Traumatic Gastric Ulcers. Brit M J 9 6 i 523

The formation of gastric ulcers following trauma to the stomach is discussed.

Surgical work with the army in France has proved conclusively the value of early operation in gunshot wounds of the abdomen. It is the consensus of opinion that any wound of the intestinal tract is less likely to be fatal if repaired immediately than when left to rest and nature although Surgeon General Sir George Makina claims that it is univose to open the abdomen in cases where only the stomach is supposed to have been wounded.

While the chief danger in intestinal wounds is from perionitis in stomach wounds it is less to be drended as frequently adhexions and the aperture and the gastine contents that do leak out are not very septic. However the real danger in this latter class is from secondary hemorrhage due to erosion of the injured tissues by the gastine just.

Immediate hæmatemens ånd melæna are rare as the bleeding is usually intra or retropertoneal However these symptoms often appear during the second week and then are to be interpreted as due to an extending ulcer of the stomach or duodenum These ul ers are the exact counterpart of the non traumatic ones with the exception that gastric insure is much more hable to formation in the track of the initial unity.

A detailed clinical report is given of the 4 illustrative cases 3 of which died 2 from uncontrollable hemorthage and one from widespread septic infection. In all 4 cases the misale either penetrated the stoma h or came so close as to cause a direct in jury to the wall. None of the cause was operated upon and hematemesis and meliena occurred in each during the second week.

In the case which recovered the stomach was probably outused and recovery from following ulcer unexpected as the rule in these cases is subsequent death P M Crissis

Verbrycke J. R. Jr. Post-operative Treatment of Peptic Ulcer and Cholecystitis Med Rec 9 0 1 vo. 74

The first step in the post-operative treatment begins at operation. Whenever possible th ulcer should be ensed kept from contamination and examined for riganisms from which autogenous vacines can be prepared and alministered during con discence.

There can be no routine treatment for ulcer after operation. The individual patient must be treated bearing a mind the possible cause of the trouble

the character and position of the ulcer found at operation and the nature of the operation itself

In cases of excision it is necessary simply (1) to regulate the det for from ten to fourteen days (2) to administer atropine or belladonna to prevent spatic contraction of the pylorus which would tend to produce further trouble (3) to make and administer autogenous vaccine (4) to avoid irritating pur gatives (5) before the patient is incharged to make search for the original focus if it has not already been located and take steps to eliminate it and (6) to instruct patients to report at least every two months for a year with a specimen of stool while on meat free diet for three days to be examined for occult blood

Not only does the l'extion of the ulcer influence the after treatment but also the conditions found at operation. A large calbus ulcer of many years duration if ever curable by rest will c retainly take longer than a small non indurated on. Perforated ulcers naturally demand certain other treatm nt which comes purely under the domain of the surgeon such as (in acute cases) th. Murphy salt solution and the Fowler position. For some reason perforated ulcers seem to tend to heal without much difficulty after the perforation is closed.

Ordinarly results in gall bladder cases may be said to be decidedly better than those following operations for uleer however the number of secon dary operations for uleer however the number of secon dary operations required and the not inconsiderable number having a continuan e or recurrence or trouble after drainage or even removal of the gall bladder would indicate that there is room for improvement in the treatm at The author believes that the reason for many of the poor results he in the fact that the original factors which caused the trouble have not been induneded.

The patient should have an individual diet list based upon the condition of digestion and the veight but in all cases fat should be restricted to a greater degree than the other food products. In the obese fat reduction should be practically absolute for a time so that the patient may use up some of his own. Some control should be kept over the fat lingest d for at least a year. If the bowels tend to become sluggish from the absence of fats mineral oil which lubricates without being digested may be given.

Next to fats the carbohydrates should be restricted Judgment is required in determining how far this may be safely carried. Proteins are allowed in sufficient quantity to maintain nitrogen us equilibrium. All of the vegetables that are desired may be taken also fruit provided the chemical on dition of the stomath does not contra indicat.

The bow Is should be kept open. If not of with will help with the addition of Carl bid prud I salt when required

Miter onvalescence excase shull be promised. Outdoor exercises such as wilking in giff reexpecially durable also pecial ido nai rises which tend to rile the fat timulit the

ti n, and correct sluggishness of the billary as well as the whole directive tract.

Post-operatively 15 grains of hexamethylenamine a day should be given for number of mooths unless contra indicated by some untoward action. One five-grain tablet of sodl m gylcocholate or its equivalent two or three times day should be administered f some mo tha.

Thyroid extract, for its action on fat metabolism, should be used temporarily in the cases in which it would seem that there was deficiency of thyroid secretions with poor oridation. Small doses should be used at first d close ttentl paid the blood-pressure and pulse. Enwang L. Commit.

Mackay W A., and Macdonald, I Perforating Pyloric and Duodenal Ulcera. Ed at II J o 6, xvi, 280.

The article briefly reports three cases of perforating pylone and dwodenal ulcers with peration One died and two recovered. These three cases were from a series of 150 operations for gastric and dwodenal ulcers occurring in the authors experience in southern Spain.

All the cases gave the typical history of duodenal

ulcer of several years standing.

In the first case, perforation occurred in the middle of a large odemators mass occupying the pylocus, which prevented the natures from bolding. Under these circumstances, the shotmen was thoroughly dry-awabbed and the pylocic portion of the storm ach belayed to the abdominal wall. Two drains through the hoision and one through the loin to the kidney pouch were used being removed on the ninth day. Uneventful recovery followed and to months later gastro-enterentomy was done.

In the second, perforation occurred i an ulcer densely adherent to the posterior border of the li er making suture impossible. The leak was stooped by an mental tag the shoumen drywarbled, a large drain put under the liver another through th lower end of the incition and a third over the publiinto the pelvis. This patient suddenly died on the fourth day affer developing a duochent fertula.

It he last case, small perforatt a occurred in an old ulers sear on the from part of the doodenum. This was closed by a single catput sature followed by continuous sature of the serous costs, and tag of gastrohepatic omenium satured over all. Following this a posterior gastro-enteratomy was done. One drain was then placed under the liver and a second bove the pubsic into the publy. These were removed on the third day and uneventful recovery followed.

The a thors strongly recommend pelvic drainage and immediate operation. P M. Chase.

Morgan, L. A.: The Post-Operati Management of Pyloric Stenosia. Am. J. Der. Ckild. 9 6 xi, 245

The author's study is based on the personal observation of fifty children who were operated on in the Babies Hospital of New York during the last two years. The post-operative results are depend ent to no little extent on the pre-operative condition

of the patient

The maintenance of the body temperature is of paramount importance. A sudden loss of body

beat has, I som instances, been the undoubted cause I collapse occurring a few hours later

The greatest danger is in the exposure incident to the operat n, and to manuscu that it is advisable to encase the infant leps and arms in non-absorbent cotton. Under the pad the operating table is placed bot water bag which fit into the small of the back and serves the double purpose of supplying warmth and keeping the site of the operation well elevated.

The removal from the infant stomach, by gain cla age, if food resid — d gas accumulation is the next most important pre-operative measure. I the post-operatic management the mainter annee of the body temperature is as before, of the utmost importance. The infant is wrapped in a warm blanket or cott jacket and the bed is well

equipped with hot water bottles

I'the tirst hou tw the head of the bed should be lowered. After oursiment his been commenced the head of the bed may be raised and from that the on the infant is kept in semi-creet position. This ele atlon assists in emptying the stomach, especially in gastro-enterest my cases, and at the same time permits the escape of gas through the mouth

Th use of exersive bypoderms stimulation after operatin a to be deprecated only one measure, namely hypodermodysis of normal saline or of glucose so loop, is always indicated and this may be safely used as a roune practice. Of the other simulants, epinephrin, subsutaneously is the most satisfactory because of the rapidity of its action caffein and trophe, bypodermatically are some-caffein and trophe, bypodermatically are some-brandy. The vain of blood transitions as a stimulant is very energiously.

A post-operative rise in temperature is to be expected in nearly alcases. No antipyretic measures are needed for this reactionary temperature, except that care should be taken not to use excessive artificial best. A pyrexis that persists for more than three days, or no that unexpectedly occurs after the first reactionary fever has subsided, about be investigated as it usually indicates some compiles then.

Feeding is the most important feature of the post operative care of infants a slight error in Jodgment may precipitat a grastro-intestinal upset that is very difficult to control. It is impossible to feed all children by the same set rule, but a general routine in of val e and is applicable to the majority of cases. The alm should be as soon as possible after operation, to start nourishment in concentrated and readily digestible form. For this purpose there is no food that can take the place of breast milk and

very effort should be made to procure enough to tide the patient over the first week at least

An hour after operation, providing the recovery from th anæsthetic has been complete, the patient is given 16 c m. of water and an hour later 12 ccm. of breast milk mixed with 4 ccm of water. It may be necessary at first to use a medicine-dropper for the administration. The breast milk is repeated every three hours eight feedings a day and is alter nated with the water Both are gradually increased so that twenty four hours after operation 16 to 21 c m of undiluted breast milk is being given every three hours and a similar amount of water between At the end of forty-eight hours the child feedings is usually taking 20 to 30 ccm and at the end of seventy two hours 30 to 45 ccm at a feeding. The administration of water by mouth during the first three or four days is of the greatest importance. The time required to increase the quantity of milk to meet the calori requirements of the child has been on an average five days in small babies three days may be sufficient and in the well nourished as much as eight to ten days

It is wise not to defer putting the baby to the breast longer than one week after operation or when the feeding from the bottle has been increased to about 60 cm This is usually on the sixth or seventh day The nursing must be carefully supervised for the next week the amount taken at each time being measured by weighing the baby before and after If the quantities obtained are too small th nursing may be supplemented by a modified milk mixture

In well nourished children a sponge bath may be giv n every day until the abdominal wound is completely healed and the dressing discarded. In poorly nourished or emacrated infants an oil rub is to be preferred.

Comiting although it is to be expected in a cer tain degree in a large proportion of the patients after operation is frequent and troublesome in some cases. The more common exciting causes of vomiting are

Distention due to accumulation of gas either in the stomach or in the intestines

Defects in the operation such as faulty a ljustment of the jejunum and stomach, or incom pl t set ran e of the constricting muscle fibers ly the plastic operation

3 V too rapid increase of the feeding

4. The ocurrence of complications especially g n ral pertennus. Of these causes distention due gas cumulation is by far the most frequent If it : mainly int stinal a colon irrigation, repeated as oft n a necessary is all that is required for relief When the ac umulation is in the stomach the head of the belish uld be elevated and the child fre quently r said to the upright positi n to allow the free escape of the gas. In patients who do not re pond t these measures it is well to pass a soft rubber cath ter into the stomach before each feeding Lavage may be employed if the vomiting is persis

tent but its use in the first two or three lays after the operation of gastr -interestomy entails not a little risk.

Repeated facal evacuations are usually not seen during the first twenty t ur hour At the nlot this period therefore it is well to give a te ispoonful of castor oil to stimulate peristalsis and remove mucus and gas. The first few tools are usually loose and green in color (r m or in) like if there has been any bleeding into the t ma hi Normal breast mulk stools are not seen as a rul until the fourth day after operation \ \ too rapid increase in food especially in hillien who have been comit ing for several weeks prior to operation is very apt to produce loose frequent stool. The measures usually employed for the relief of acute intestinal disturbances are applicable to the condition

The dressing at operation should consist of a narrow fold of sterile hause which just covers the incision and is held in place by a thesive strapping there is seldom any indicate n to disturb it for the next four or five days A binder hould not be used. The advantage in using a small fressing is that the least hemorrhage can be realily detected and controlled. The titches may be removed on the sixth to the eleventh day lep nding on the condition of the wound and aft r that a protective

pad of gauze is all that is required

Of the 36 infants discharged in good condition 4 died from a variety of auses none of which vere directly associated with the operation. The deaths occurred two weeks after discharge in two instances and two months after discharge in the others. Two children were lost sight of and of the r mainder 10 were followed for one or two years after discharge 13 for six months to one year and 7 for less than ar months. EDWARD L CRY L

Bradford W H Chronic Gastri and Duodenal M = 13613

The results obtained from surgical treatment of patients suffering from chroni gastric and duodenal ulcer have been among the most satisfactory in all the author's surgical experience. The mortality has been exceedingly low A man with acute perforation of a chroni gastric ul er died one week after operation. With this ex uption no deaths have followed surgical treatment

Among his successful cases the following may be briefly mentioned

A male aged 30 was operated on 1ght year ago for a large pulpable mass diagnosed as gastric cancer and is now pertectly well

A male aged 5 had be a suff ring from ga tri ulcer for seven years. In M 1914 he had the pylone half or his stoma h remo I and ha gained 55 pounds since operation

I male agod alout to had been t king medicine for stomach trouble for thirty years he was in ciated and aniemic. He w operated on for luode nal ulcer n Novembe ora After oper ton his improvement was wonderful and he had no further need of medicine. EDWARD L. CORNELL.

Mills, R. W. Observations on Duodenal Ulcer with Special Reference to Its Y Ray Diagnosis. Interst M J. 9 6 xxiu 68

The stomach in uncomplicated of odenal uler ig generally condidered to be characteristically hyper toule. Hypertonic stomachs are haracteristic of those of subsuch shabitu consequently either the stomach in duodenal ulere becomes ab mully toule, or duodenal ulere occur in those ho aturally have hypertonic stoma hs. Mill thu kn. naveilgation will suggest that both are tru. should certain complicating f. t. n. rist the g. tru. hypertonic of duodenal uler ni lost to g. tge comm naurate with that f. the omplicating f. t. commandate with that f. the omplicating f. t. Such factors a. d. odenal sterooms entil g. f. om uler and general conditions causing at v. as general debtility from hemorrhage and the like

uncomplicated d odenal uk there is a ellknown increased initial motility early and free pyloric outflow With stenosis motility is tarded and there may be a six hour ret tion. C p d formity is by far the most valuable and const it duamostic indication of duod nat ulcer Callons ulcer situated in the first part of the duoden m is impossible without characteristic and per intent anomaly as to the firm of the cap and is t times added to by spasm. A perfect cap means n callons nicer. Deformity may also occu as the result of adhesions t due t ulcer The contention that mall ulcers can exist w thout cap deformity is in dire need fillumination through llustrated specific case reports. Certain peculiarities of gastric perist lais occur in uncomplicated duodenal ulcer which were not anticipated before the advent of the I ray We have heretofore know of but one clinical condition resulting in visceral hyperperistalsis. namely atenoxia

In uncomplicated duodenal ulcer gastric hyperperiashis occurs immediately o shortly after the ingestion of the contrast meal, or only after the ingestion of the contrast meal, or only a though atenosis distal to it, but with a decrease in the resistance normally offered by the tonus of the pyloric sphure. Millis thinks that all indicated as an universidate to the idea that the pain of duodenal ulcers due to hypertension in eithers in machor cap the so-called dequate stimulus of vasceral pain, but that it is due rather to the nerve-endings in the ulcer-flow becoming actually and ab ormally sensitive to excess of indrochloric and

ALBERT MILLER.

Woolsey G The Surgical Treatment of Gastric and Duodenal Ulcers. Med Rec. 9 6 lvvux, 50

Woolsey advises a thoro gh trial f medical treat ment fo gastric and doodenal ulcers, and at tes that acut ulcers will almost all yield t toolly cases of perforation requiring surgical treatment. The symptoms due to chronic ulcer will in time subsid with r without treatment. B t relapse is the rule and there is some question whether medical treat

m t gives permanent cure. After two or more relapses have occurred urgery should be resorted to. Gastro enterostomy is the operation of choice. It affects both the drainage and the bemistry of the stomach the acidity is diminished by the presence of a small quantity of bele and nancreatic secretion the pylorospasin is eleved and the stomach emptes itself without irrit to f the ul er by the passage of food. Heal ing occurs in 8 per cent of ages (P t non) Symptoms will persuat if due to dhenoms or malignant degeneral n. Gastro-enterostomy is of certain pre il f perforatio harm rabage but it I minishes the probal lits of thei occurrence On crount f the anat m! I tructure of the d oden m ul em of the ant ri r d odenal wall can be overlooked and search should also be made for of inf eau at cont a ulcer on the posterior Il which is more durated and of the eastrice type Cases where the pylorus is stenosed give the best lat results

The v rous methods of operation are () Von Encladers a the most radical in which the stomach is divided proum it the uller and both ends sittured () Wilms, in which band of fasci half an arch wid is fastened tightly cound the stomach pounsalt the ulter and (3) the method of infoldingth project end by ture.

Soc dofenal ulcer almost n ver undergoes malignant degeneration gastro-enterost my with without plyori clual in give excellent results. It is different in cultous gustine inferens, which of infrequently become malignant it is sometimes impossible to differe that between an i durated ulce and carenoona. A radical removal of the

chronic ulce best in such cases.

The two complications f gustro-enterestomy recoust direle and peptid jejunal ulcer usually of the stoma are oded by proper technique. The

the uses fine ch omic gut for both s ture layers. The more radical operations for gastre uker are exchon, pyl ne resection, and mesogastri resection Excesson is not satisfactory operation. Resection is more radical but gives better results.

Resection is more radical but gives better results. I ulcers of the pyl no region of the stomach, the Billroth method is the operation of choice It should be followed by gastro-enterost my or the Flya Reichel modification is which the protunal end of the stomach is rutured directly: the feju mn. The chief technical difficulties are due to adhesions, especially in case of penetrating ulcer. When the ulcer is farther from the pyl rus, usually on the lesere curvature the mesographic resection or resection in continuity is the perait of choice. The mortality of resection is greater than that of gastro-enterostomy but the operail in it well borne and the mortality pook high. It all cases of gastric of duodenal ulcer the peak t should be put of a special disc for some time after operation.

The so-called hour-glass stomach which results

from a cicatricial contraction of a gastric ulcer is treated on the same principle as callous ulcers

The two complications of gastric and duodenal ulcers ar hamorrhage and perforation. Sudden a ute horn rrhage is usually due to acute ulcer and is best treated medically In recurring hæmorrhages with threatened severe anæmia operation should be done before the anæmia pr gresses In cases of dangerous hæmorrhages dir t transfusion of blood is of great value In acute perioration carly diagnosis and immediate operati n are most essential

Subacute an I chronic perforations result in peri gastric and subphrenic abscesses which demand ac urate diagnosis to indicate the operation suit able t the case L R. Goldsvitte

Haines, W D Some Features in the Management of Surgical Disorders of Digestion La 0. (35

The newer pathology has shown that the organ isms of an injection occurring in the buccal cavity th t usils or elsewhere may be transmitted by the lymph or blood stream to remote parts of the body ther to form new foci when arrested in the terminal ves 1 of su h organs as the gall bladder stomach duodenum brain or kidney According to thee newer concepts digestive disorders gastric ulcer cholecystatus and appendicitus are to be regarded as terminal infections Gastric and duodenal ulcer mu t be regarded not as a disease but as the end result of a disease To successfully cope with the symptoms the original source of infection must be remo ed Pus must not remain unchallenged any where in the system.

The author is convinced that o per cent of directive disorders may be cured by removal of some extragastric pathological condition the source of the disorder being an overloaded colon, infection of the pancreas gall bladder gums, sinuses or tonsils

The mortality following perforation of an ulcer increases by leaps and bounds after the first few hours and immediate operation is imperative. The thick indurated mass associated with chronic preny loric ulcer should be removed but these patients are in such poor condition from prolonged starvation that they are poor surgical risks and the better practice is to d a two-stage operation a primary gastrojejunostomy nd a s condary resection after recov ery fr m starvation. Occasionally one finds that the mass at the pylorus has entirely disappeared. In this case the second operation terminates as an explorati n

France J Enteric Intrassucception. Edinb II J 9 6 xvi, 175

Two cases are briefly reported in whi h i tussusception occurred bove the decorcal valle, complete recovery following operation. In both the symptoms were greatly similar

In both the symptoms were greatly similar showing early coik-th and minal pain slight nauses, increasing consulpati n, rising temperature and pulse-rate, with abdominal distents and ngid ity. In either was the presence of blood per retum noticed and general prostration occurred early. The age of the first was three and one half years that of the second ten years.

In the first case th Intrassucception was found about ten inches above the Beocard valve. This them was invaginated into the large bowel the Beocard valve remaining at its pex. In the seco of case, the intussucception involved about twenty inches of fleum, extending t within twelve inches of the Beocard valve.

of the necessary resection of the involved fleum was performed followed by end to-end ansatamous in the first case recovery was complicated by acute parcetils and later by a condition resembling pollomyelitis recovery however occurred. In the second uneventful recovery took place.

The author emphasizes the age, the gradual on set and the absence of blood per rect m. The latter is almost diagnostic of enteric intussusception

Johnson, J. E. Conclusions in th. Study f Intestinal States. Seath M. J. o. 6 in 148.

The uthor traces his experience with cases of intestinal stans, beginning it in stage where the appendix alone was removed to what he terms the blackest page of disapport timent. In this cardeavor, the mechanical correct! of the various picoes and

the mechanical correct! of th various proses and kinks discovered in this condition. Finally comes the physiologic stage which offers most hope f r the proper understanding of this condition.

There are three planeters I the gastro intestinal tract the pylorus the Becorcal valve and the ampliancer. The function of the pylorus is to hold food in the stomach proper length of time — 45 hours — for its preparation for intestinal digestion. If held longer by obstruction or spasm — the pylorus it becomes n urfied and the intestinae consequently

absorbs had food. The execum is the cesspool of the intestinal tract. If the ileocæcal valve be in competent there is regurgitation and the patient literally feeds on his own excrets.

The auth r points out the effect of irritation on one of the sphincters in its ratiation to spassmoof the sphincter bigher up. The most common example in pri repairs due to thoronic appendicitis. This condition will cause a delay towards, the points of disposals of which are repeated soreness in the right soft preceded by toxic bendaches without the contract of the condition of the contract of t

The totenth of fleococcal regurgitation is quite different from the toxemin of delay. The former is the cause of viscroptosis (through toxic paralysis of the planchnic nerves) and the formation of in flammatory membranes due to bacterial invasion of the walls of the intestine. The cure for fleococcal regurgitation is a plastic operation described by the author in previous paper for the re-set blishment of the function of the deconcel valve E. Facent.

Hubeny M J Roentgen Examination of the

Appendix. Ill sess M. J. 9 6 mx, oo.

Roentgen examination has eliminated some of the possible errors: it diagnosis of chronic appendictis. Hubeny gives some of the confirmat ry data which with the chincal findings warrant this

diagnosis.

The flu rescopic examination is the most satisfactory and visualization f the appendix is pre-

ferably made by opaque menl

It is eccessary that the appendical lumen be put
ent, otherwise the ppendl may not be demon
strabl

Some observers think that every appendix which permits the entrance of an opaque meal is pathologi however if the ppendix empties itself at the sam, tim, as the encum it must not be so considered.

Adheasons are considered as pathological evidence of previous unfainmations. These may be fit rescopically recognized particularly if extensive, oc tractions of to structure of the lumen and other results of a daseased conditi n can also be demonstrated. Much lift mation may be derived from the sue if their conditions of the visualized pope dir.

Since it is well k on that saide from gastriulcer chronic pipendialitis in the most freq ent cause of spatamod hou glass nint it of the stomach, this as well as ther effects on remot organs, may be looked for H it in E. Porriss.

Morris, R. T. Pibroid Degeneration f th Appendix. J II Sec. N J. 9 6 vm. 20

Among four well-defined types of appendicitis, fibroid degeneration ppears t furnish the common est leaton. It is an irritative leaf n, not infective. Individuals of the authenic group presenting a

number of stigmata of decline appear to have fibroid degeneration of the appendix more frequently than do other individuals of normal development Patients with enteroptesis and with the features of arrested development belonging to viaceroptois are prone to include symptoms of hibroid degeneration of the appendix along with their other symptoms.

The signs which belong to fibroid degeneration of the appendix the irritative lesion, the common-

est form of appendix trouble are

Transitory pain and discomfort in the appen diceal region, not sufficiently severe to send the patient to bed and extending over many years

2 Hypersensitiveness of the right group of lumbar ganglia, determined by making deep pressure upon the abdominal well about an inch and a half to the right of the navel and a little below that point no a ompanied by similar sensitiveness of the left group of lumbar ganglia

3 Habitual distention of the ascending colon with gas

4 Various gastro-enteric disturbances partly due to irritative influences from the appendix and partly due to other features of neurasthenic habit or arrested development such as sagging colon loose kidney and complications previously sludded to Lowest L. Corrett.

Dubose F G Neglected Appendicitis: Its High Mortality a Diagnostic and Therapeutic Responsibility S ik M J 19 6 ix 332

The unduly high death rate from appendicitis, given in reports of insurance companies as compared to the exceedingly low mortality from early operation in acute appendicitis makes it incumbent upon the physician to enlighten the laity upon the possible extrousness of what appears to be a bellyache

I nder the title pathology the author accepts and quotes freely from the report of Stanton All cases represent merely different stages or degrees of inflammati n The second day is considered the most serious and Dubose says If it is going to or ur at all gross perforation of the appendix itself with or w thout gangrene usually takes place before the end of the second day Attention is called to th onclus a Stanton reached denying the exist en e oi catarrhal appendicitis as a pathological nuty and aft rming that bacteriological perforation or ur luring the first few hours of the attack whith r or not gross perforation of gangrene Movnihan and Deaver are freely i pr sent quoted a pointing to the direct connection between perf ation and spreading peritonitis and pergation In I the heading symptomatology after de sortling the usual well known symptoms and signs utho states that the differential diagnosis lies not between a ute appendicitis and acute in dig st in but between appendicutes and some other con lition demanling surgical interference. It is only the neglected cases which I man I m t careful ju igment as to when is the best time to operate

In coming to a decision the surgeon must always bear in mind that what has been done before he has been called and what can be done post-operatively have as much bearing on the ultimate outcome of the case as the operation itself. If a late operation is unavoidable the author advises that the stomach be emptied and kept empty that the large bowel be cleaned with enemata and be prepared for the use of proctoclysis that in rphine in sufficient quantities be given to relieve pain 1 seen puristal sis diminish shock retard absorption limit tissue waste and to favor the formation of protective peritoneal adhesions that the patient be put in Fowler's position and that proctoclysis of 15 per cent plucose i per cent sodium licarbinate and o s per cent sodium chlori i be given. If operative delay be unavoidable the author gives in full his reasons for never administering a purgative for withholding all nourishment by mouth and for the administration of morphine

In case more than forty-eight hours have clyused between the onset and the time when the surgeon is called immediate operation is imperative (i) if all unfavorable symptoms become cascerbated in spite of the starvation rest treatment (i) if there be sudden rehef of pain with subjective better ment but with a quickened pulse rate indicating rupture of the appendix or of an abscess or of thrombosis (i) if a circumsanbed swelling appears in the right abdomen (evilence of localization of inflammatory process by additions) (i) if the previously high leucocyte count tail auddenly or gradually declines with a steady increase in the polymorphonuclears (c) when more than on week

has elapsed since the onset

Operation should be deferred from the third to the seventh day after onset long enough to give the starvation rest treatment a chance and should be deferred as long as the patient shows improvement under this treatment in the presence of a blood count which shows a high polymort honuclear count without a corresponding leucocytosis which is indicative of intense infection or of a patient with low resistance so overwhelmed that a fatal outcome is to be expected under any treatment The bene its derived from delay are the recovery of the sympa thetic nervous system from sho k the blood is given time to form antibodi's and the perstoneum is allowed to form limiting adhesions The dangers in postponing operation are further saturation of the system with toxins especially in the presence of a gangrenous or obstructed gut bacterial invasion of the blood stream lymphatic infection with result ant empyema, subphrenic abscess, multiple abcesses of the liver or cholecystitis progressive suppurative pentonitis

Of the factors influencing the outcome rational pre-operative treatment is the most important in favorably influencing the result of operatio. The anisthetic of choice is nutrous-outde-oxygen lone or combined with inhitiation. The operation should be well planned. The author describes an

incision which he has proved to be very satisfact, rv. The akin is incised transversely through M Bu ney's point, the aponeurous and muscles are divided in the nexal way and the perito cum opened if more room is required, the lused poneurosa the outer border of the rectus is cut destruied don word, thus permitting a triangular fl p t be raised and as extensive an exploratio as m v be desired. Every pus pocket is opened and d at rel the mendix is removed in every case where at all feasible, and thrombosed or gangrenous me i m is likewise excessed. Sheets of rubber t wu gauge icks overed with rubbe tesu used for drains. The autho believes that to is the errors of appendiceal surgery result largely from timidity or conserv tism due to lack of under standing of the pathology underlying the pict re

At the close of the operation hypodermodysis is given suppl mented by proctoclysts the pat it is placed in Fowler's position, and morphin in suffi cient quantities to relieve pain is administered hyper dermatically Stomach lavage should be use! every four to at bours, and where duodenal in tent are regurgitated, the stomach to tent at tained by layage are re-introduced in the proof | aus. Essence of pensin, one teaspoonful t quart of water is administered per rectum t reliev gns. Pituitrin is used for distent! fter the th ! day when it is first permissible t stimulat penstalsis. Milk and molasses, equal part re the safest ingredients for an efficient purgat ve enem The routine use of strychnine casseine parter nitroglycenne, and strophanthin is ondemned Morphine atropine and pituitrin have distinindications and are valuable when properly soil Glucose and soda administered intra nously make an ideal heart muscle stimulant bes des affor ing nutriment and acting as aids t the elimination of torins. The post-operative care is equally as important as the operation. II TOTO

Andries, J. H. The Choice of Tim. for Operating in Acute Appendicitis and Gall Bladder Diessa. J. M. ck. St. M. Sec. 9, 6. 8.

In acute appendicula ca ly operation is the local of centines the only chance of cure. In the patient is not seen until the third day of later to best to postpone operative treatment with the local is circumscribed and localized. The danger to the lift of the patient is greatest if operation is performed on the third or fourth day. After the fifth day there is no longer ory danger if it is treated simply as an issees. If pounous complicates care it permits the tended hoods is poor and the co-dition had best be treated non-surgically—and the pneumona subsidies.

Appendicith during pregnancy is also a very grave condition, the more I vorsible cases being those that are operated upon during the first few bours I the tt ck. In every case of ppendicitis in the male the physician should satisfy himself as to the possibility of pregnancy as such a complication is always hazard t th pat cut s life.

In a part of the control of the cont

tra-t it it if it the temper ture is above rozcept in those cases of greatly ditended gail-blad. It where rupt re is immose to lifere all that is necessary is neuson in drainage removal of it ness by any neuthod und these circumstances being dispersors.

Thus I is seen that in both affections the choice X time for operation runs parallel, an early operation being eccessary to oid progress I pathology it lessen the difficulty oil seriousness of surgical centreent and timinimize the danger to the pat ent bit. E. K kenerge G.

Wiener J Appendectomy Under Local Anses thesia. J in M 4m 9 6 km 78

The technique hich the tho employs is as fill w.

Half an hour before the operation the patient

rece is quarter f a grain of morphion hypoder matically A pe ent sol tion f movecame is used it an ounce of which is died to dropp of the open constitution of the solid configuration of the solid control of the solid co

most cases cut as well as hone. This in casion is particularly adapted to the per tion ader local mesthesia. The ski near the terror su peri pr is not very sensit bit by f the greatest d antage of an incis n thus location is th fact that it comes directly do on the ciecum. Rarely is t necessary t pack as the mail i t stines (although this can read ly be done a thout causing par) and there is thus less handl ne of the test nes Th vocaine is first injected 1 to the kin along the lin of the proposed incision. In doing this the uthor tries t blauch the kin a think fected sol tion. Then the novocalne is I jected under the skin all ng the same line

After wait of three mi use, th kin nd subutaneous the ear are paniessly in cased down t the aposeurous of the external bilion. A sharp scalpel is used for dividing all layers, as estisors, being blunter than a knife, are more apt to use pain. Next novocation is injected under the external oblique aponeurosis of after two minutes that is divided. The solution is next injected in the internal oblique muscle, parallel to the fibers of the muscle. Mee another wait of a f w minutes the internal oblique is up parallel to its libers. A bittle novo-came is then injected un let the personeum and an internal of fulls there, minutes is allowed to clapse before di iding it. If ione in this way there will be no pain uj to this point. If manipulations should be as g nite a possible. It is triefly necessary to apply artern forceps in opening the abdomen through this incision which is an additional advantage as the crushing of the blood v-seel with forceps may cause some pain unless the novocame is injected ar und the vessel. If n v-ssary a packing can be introduced to keep the mail intestines out of the way although it is rarely necessary with this in caston.

As soon as the amount with the appendix is ex posed some novocaine is injected into the meson tenolum. If this is not done the patient will complain of cramplike abdominal pain referred to the navel or pit of the stoma h By ansesthetizing the mesenteriolum this pain is obviated. After a wait of thre minutes the appendix can be pulled out of the abdomen the m's ntery ligated and divid ed and the appendix removed lith almost no pain It is not necessary to inject a vocaine into the base of the appendix before ligating and removing it If the mesenterk lum is properly anaesthetized there will be no pain during the removal of the appendix It is perfectly feasible to draw the right tube and ovary into the wound and do any operation on them that may be indicated

The abdomen is closed layer by layer in the usual manner and if the technique has been correct the losure at the wound will be entirely painless.

COWARD L CORNELL

Landsman A \ Anorectal Flatula. \ \ 1 \ M J

The case reported is that of a mill colored ge 46 contilumng of a crucial ng pel 1 pann pa with malin hara 1 r loss f weight waken and g n eral 1 bility. On wamin tin tital lusin of

the rectum was found, extending upward from the prostate for about five inches. The mass was hard and bled easily No enlarged glands were pulpated.

Median abdominal section was performed, best on here metastases and no glandhair invol ement were found, the growth being entirely extraperitioneal. The bowed was severed well above the mass, stern lized by phenol and alcohol, and closed by purse string sutters. The rectum was freed by blant dissection and the perfectal time completely removed. The rectum was them out at the internal sphaneter which was touched with phenol and alcohol. The cavity was drained through the anna by a large rubber tube small tube was inserted through an opening posteroidateral to th anns and "ew atripa of rodolorm gause inserted, after which the abdomen was closed.

On the third day bacilius coil infection developed which was checked by irrigation through the anal tube, but the patient died on the eighth day. No nost-moritem was obtained

The pathological diagnosis was adenocarcinoma of the rectum.

P M Crass:

Morley, A. 8 Th Trentment of Hamorrholds by Injection. Leacet Lond 9 6 tc, 6 7

The obvious advantages of the treatment are () that the patient need n t be confined t bed for more than 24 hours, at most () that there is o need for general or local angesthesia since the treat ment is practically painless, if properly performed (a) that it can be mad out mexpensiv som h so that it may be brought within the rea h f even poor patient who certainly could not f ce the pense of an operation in a hospital (4) that it is perfectly saf procedure in such patient as the very aged, pregnant women, and thers, who f r som reason cannot take an anzestheti safely ch as persons with dangerous heart or I ng diseases (c) that there is no after-pain and (6) that it is in anably harmless.

The treatment is not suited to cases of strangulated or irred cible hemorrhoids t cases in which there are their c mplicating cond t ons, such as old-standing fissures, fixtule ulcers t

as old-standing fistures, fistule ulcers t
The treatment consists of the injection into each
internal pile of a few drops of carboil old and
glycerine The i flowing sol took is employed

Acid carbolica gr xivili Glycerine d ii Aquae destillat dr ii

The amount which should be injected it each pile suries from to 6 minims of this solution. In ject all the piles at one ditting whenever it is possible to do so. It is easiest and best in every way, begrown the injection through large speculum. The one most suitable is Kelly's spheneteroscope. The other neefful applaines is a suitable springe.

Before making the injection, the piles may be sponged over with a little weak biniodide of mercury o 1/50 lysol solution, which should be mopped up at once with a dry swab to prevent risk of absorption. It is a good plan also to touch each pile at the spot where it is proposed to inject it with a drop

of pure ca bolic.

The patient should be instructed to keep quite, in bed if possible for the first a to as hours and to wash the piles at o ce with cold water should they prohapse and them to greate them well with vaseline or some simple outstment and gently press them back. Where the piles are large, as many as four or five injections at weekly intervals may be required b t, as a rule, two or three re sufficient

EDWARD L. CORNELL

Edwards, F W Th Treatment of Hamocribolds by Injection Lauce, Lond 0 6 crc, 8 0.

The author refers to the fact that Van Buren was one of the first to advise the treatment of hemor rhords by I jection. He has tried out the method some hundred cases and seems well satisfied with the results. Except in two cases there was o pain. O e injection sufficed to cure some, but the majority required two or three. It failed in one or two cases, which later required excesson and ligation. He uses to per cent carbolic acid in equal parts of glycerine and water. Havi g protruded the piles, the patient is placed in the knee-elbow positio and an injection of from 3 to 6 minims of the carbolic solution is made int the center of each pile. In some f the large piles he injects 5 ml ims in two places. The piles are then well smeared with vaseline and repla ed as soon as possible, for the injection alw vs causes the harmorrhoids t swell. Bowel moveme ts are prevented for forty-eight hours, nd should prolapse occur in the meantime, immediate replacement is necessary

II mphasizes th importance f protruding the pales befor attempting the l jectio and gives as his reason the following (1) It is much easier and one is more certal of getting into the center of each pale. () If the pales are injected through a peculum a special l ng syringe is eccessary whereas an ordinary hypodernic syringe suffices when the piles are prolapsed. (3) Piles which cannot be protruded should be left alone. They are to be cured by pallistive means such as local pplications, enemata, the ti to diet, regulation of the bowels, etc. (4) An assistant is almost necessity if a specul in is used, and should any bleeding occur on the withdrawal of the needle, is indispensable. He does not believe that this is as likely to take place as when the piles are prolapsed but it might occur when n extra pair of hands would be useful.

Case fitted for injection are those of uncompil cated internal homorphoids which can be protruded, then returned and kept within the bowel, so that comparatively few cases are fitted for the injection treatment. For instance, in class of a day's experience in his dialic in which placeted by other led may with fassure, a with cuter and piles—with an anal ulcer and it with a throm bosed internal pile. After the injection a few hours in bed are a ivisable, after which the patient can walk about and attend to his u unl scupation

The great advantage Ldv ards sees in the in jectu in treatment are (1) n innnement to bed excepting f r a few h ur when possible (2) n) anistheti i needed theref r there is n pot anistheti v miting (3 n pain 4 n enforced absence fr m husin as operatt in it elf and n risk from the little operatt in it elf and n risk from the little moreasing betterment.

As regard per tive treatment he is a trong advisor of the ligature peration and condemns the Whit head operation. Drong C Bur tra-

Burrows W.F. and Burrows, E.C., New Hæmor rhoidal Operation the Snare and Bullet J. Let M. 1. 1. 1. 8

The ham rihoidal operation described is simple rapid fr e from danger suitable for the use of local anasthesia and has been used in a senes 160 cases

The instruments required are a hypodermic syinge and breal anaesthetic half a dozen arrey frceps to pairs of sot sors—ne pair for cuttin the wire, four in trand fisting plable vire bit hends of each strand threaded through a perforated lead bullet and a bullet hiller and crusher. The operation in resembles most the ligature method but is cleaner in re-th-rush and in re-quickly carried out than the latter. The pile as be cutaway of erito the snare than the ligature and the snare and bullet finally he at a hipper level than does the ligature with h the inagers must get into the anal canal to be a procedure that is difficult.

The tip u t be removed are thoroughly and thetized with the local anies bette fluid and an incision is made below and to either side f the extro-internal hæmorrh id extending into the rec tum and di ading the desper tissues in a mey hat the form of a V cdre A pair of f rceps previously applied t the tis ues t be rem el i used to evert gentle traction on the parts expr sing more of the rect I muc sa proper A second pair f f reeps is relaced in the rectal mucha and again traction is made in the mass and the lateral inci i no are extended in art to the lerrice desired. Tho e th last pair of f re ps a transverse inci ion is made in the mucous membran a point of some importance since it is n the lit that the are will sink and prevent shift no A wire loop threaded through the perf rated bullet and its free ends held in a clamp t then hipped over the handles of the f reeps at tachedt the hem ith illand the lipplaced in position with the f reinger While the vire I sop is kept taut th full the grasp d by the bullet hold r and crush ran ! forced do n on the muco a to either the skin r muco side of the pedicle (prefer 1 ly the latters thus to bteming the snare. The type f peration h h th aith remply at the gall bladder and right fre be driven the gall bladder and right fre be driven to save the gall bladder and right fre be driven as the gall will do of the edge of the band the full du of the gall bl dler are griped the highly half of gall the first gall to the gall the first gall to gall the gall the first gall to gall the gall the first gall the gall

piece of most gause, and are pulled downward, outward and then upward, making the cystic duct and the free border of the gastrobepati omentum taut A small incled is made through the upper part of the border of this m ntum and the duct exposed. It may who clamped at its function with the gall bladder and cut across distal to the clamp with the cautery The comm duct can readily be explored by passing a probe through the stump of the cystl duct ibt the duodenum. Before the probe is remo ed the duct is pelpated between the fingers and th mb of th free hand, so that no stone is overlooked. The cystic artery lying above nd t the inner side of the cystic duct is next clamped and cut. If it is not pecessary to drain the common d ct the tump

of the cysti is ligated and next the cystic artery The gall bladder is freed from below pward. This is done step by tep following closely with continuous suture of cutgut which passes through the liver tissue forming the sides and floor of th gall-bladder bed. In this way the operat on is a bloodless one and the author regards it as supersee to packing with gauze or to placing a cigarett drain in the cavity left behind. The divided I yers of the gustrobenatic omentum are sutured, not covering in the stump of the cystic d ct. A mall rubber tube is placed just beyond the free border of the gastrohepatic omentum and is left for four or five days. Should the stump of the cystic dues leak bile, this t be may be left in pla 1 ger (TENOGO

O Brien, F W Th Present Status of Gall-Ston Diagnosis by the Roentgen Ray Best II or S J 9 6 deady 300.

O'Brien reviews the literature, paying particular attention to the works of George and Cole. I his wn work O'Brien uses fast finely grained, intensifying screen in all gall bladder with. The advantage of employing screens is that of time as well as intensification. It is f adamental work that the patient should not breathe during th exposure Stout indi iduals may find it difficult t hold the breath even for second, bence th rea son for speed. The screen, too will catch more surely the markings of the so-called soft gall-st near It is again of special value in the robust of comulent where long exposure on an unwreened plate would give rise to so m ch secondary radiation that the gall-stope shadows would ctually be lost

The positive fith tube will depend posith position and size of the patient but usually timin plane parallel t that of the patient s body. A small diaphragm and small cone are very important f ctors in the successi I search for gall-st ea. One objection to the dusphragm and small cone

is the liability to verlook at nes in bnormally placed mil-bladder so that it is well not to confine the search for sto es to the commonly accepted location for them. They may be found anywhere

in the lower or upper tight quadrant and even to

the left of the median line

The importance of using a saturactory developer eed not be mentioned. More than that o e may with advantage overdevelop certain plates whil giving others thes small developing time. Plates that re too dense t be read may be re duced d in that way gall-stone had we may be detected in the process of red ction that would not be likely to be found in any other way

The plates should be read ally when thoroughly dry D eet illumination by the rthern sky is

ofte particularly helpful

That apenence is a tremendous asset to successf I diagnosas as treated by the number of roentgenologists who inder the impetus of the recent di vances gall-stone diagnosis, have gone back over their old places of the gastro-intestinal tract and gall bl dde rest n in which they have reported no evidenc f gall-bladder calculi nly to find on rest dy very definit evidence. FRACTURES AND DISLOCATIONS

Skillern P G Jr The Diagnosis of Fracture by Physical Examination Versus Skingraphy Inter t M J , xxm st

By obtaining a careful history of the mechanism of the injury and by a bri t and gentle physical examination with the elicitati it of true wincing tenderness the diagnosis of fracture can be established in the great majority of cases without the air of a skiagram

The chief value of a skia ram consists in checking the extent of the deformity. A skia ram must be consid red merely as one of the many signs of fracture

It is m re-difficult to diagnose contusion and sprain than to diagnose fracture. Such diagnoses are often but cloaks to cover hasty and incomplete physical examinations and should presuppose negative results follo ing the exhaustion of every means at command to pr e the presence F D Dicks

Elkenbary C F The Fracture Problem \ orth 1 St d , t က

The author in this general paper all attention to the senousness of c ery fr ctu. H lays stress upon proper alignment and t relation to function. Between the open and closed in thods of treatment be thinks there is a happy medium.

If advises the open treatment in fractures of both bones of the leg r arm with irreducible over riding fracture of the femur with over riding-fracture of the patella and most fractures f the observation. If there is no infection, operation is indicated at once. Missage and manipulation should be begun at once in the closed, and after few days in the open, operative treatment in compound fractures the operates at once. In ununited fractures the bone-graft is recommended.

E. B. Microsco.

Rosenzweig, S. B. The Causes of Prolonged Disability from Fractures. V F 1/ J 0 6, cd, 640

Rosensweig urges that as m ch care be given to the prevention of prolonged disability after fractures as is given to the various operative procedures

used in their reduction.

The causes of prolonged disability may be general or local. The general causes are less frequent. Among the most important are cachering, as in tuberculosis and malignancy of the severe america circulatory disturbance, as in cardiorenal or hepatic diseases nervous disorders, as in tabes, parents, or myelitis. Old age is also important.

The local causes are divided in: three groups () amount of bone injury and damage: soft parts, (1) the sequelax of poor reduction, maintains, delayed fibrous union and non-union, and recess of callus and its results (3) the result of insufficient or improper care such as pressure uleers muscular strophy ischemic contracture and adhesions within the joints and tendon sheaths. LLOTO T. Brown

Henderson M S. Th Transplantation of Bonin Ununited Fractures of the Shaft of the Humerus, A s. Surg. Phila 9 6 bill, 464.

Henderson reports to cases of ununited fracture of the shaft of the humerus operated pon at the Mayo Chnic, with the following results. In 4 cases union was obtained at the first operation, in a second was necessary in a no data could be obtained as to the final results, and in one no union is known to have occurred. In cases there was primary musculospiral paralysis produced at the time fracture occurred. In one no attempt to trace the nerve was made in the other the severed ends were encased in fascial tube made from the fascia lata, the operation being too recent to stat the result. One case developed the same kind of paralysis at the time of operatio from too vigor ous retraction, but at the end of one year full function was restored. H arrives at the f llowing conclusions

The transplant must be as large as is practical (6 inches by one half inch or larger). It must extend well past the thinned decalcified ends into the hard healthy bone beyond.

2. The inlay is the method of choice.

3 Adequate post-operative fixation is necessary A split plaster-of Paris splica prepared a few days before operation can be fastened on with adhesi e strips immediately after the operation is completed thus eliminating the difficulty of applying the splica and the danger of disturbing the grait thereby. Two or three weeks later when the wound has besied and the stuckes have been removed, a new cast can be applied carefully with the patient stiting up.

4. By removing the booe-graft from the internal, that surf co the tibla the trong crest of the bone is left to perform its important weight bearing funct in The petitent may be allowed to walk in from the days and by this time the blood-clot dilling in the bony defect has become sufficiently organized so that no harmorrhages will occur when the leg is used.

A properly applied spica cost may be comfortably worn for 3 m nths when in all probability union will be complete.
 R. S. Brouza.

Hawley G W A New Method of Fracture Fixe tion Interd M J 0 6 xxii, 7

Hawley describes a method of clamping oblique or transverse fractures by means of wire in such a way that the wire may be withdrawn from the wound whenever desired without disturbing the fixation or making a fresh incision

The instrument consists of log slender bar aloop of beary woven broas or ordinary picture wire attached t a sisking clock and thumbacrew. The wire loop is designed to endried the bone and engage the nd f the bar to form a false knot. By turning the thumbacrew in o e direction the loop can be tightened, and by tu ning in the there of the control of t

From experience in 7 cases the thor concludes that the instrument has its field of usefulness in instrume where there is much tendency t displace ment. A f w cases have become infected, but only in a mild degree, and healing was without incident.

F. D. Decrease.

Simmonds, B. S. A Method of Treating Gunsh t Fractures by an External Fixation Apparatus. Brit J. M. 9 6 1, 48

The author describes an apparatus for holding in position the fragments in compound fractures. By means of an asceptic operation he inserts into the bones at a distance from the seat of the fracture screas which are long enough to project well be yould the skin and to immobilize the fragments by means of a rigid plate fixed to the screws by nuts the entire operation being done without interfering with the original wound

The advantages of the method are (1) the apparatus is simple and inexpensive the operation is simple and easily performed the original wound is not interfered with and healthy tissues are not extensively opened LLODT Brown

SURGERY OF THE BONES JOINTS ETC

Cohn I and Mann G A Further Study of Bone Repair Suik M J 9 6 35

The authors give a report of studies in bone repair from experiments done within the last two and a half vent. The literature sin e 1073 is reviewed and grouped into two schools one in which claims are made that periost um makes bone and the other in which claims are made that periostic mode in new bone formation. The conclusion from the study is that the periosteum is a means of protection against infection a source of added blood supply a limiting membrane and its presence favors an earlier repair of defects but the healing in its absence is bony invertibless.

The authors found that free transplants of periosterm in the anterior chamber of a cat's eye did not hye and produ e bone. Free periosteum wrapped around the carotid artery showed no growth of bone Resections of the fibula subperiosteally leaving the closed periosteal tube behind gave no regeneration of the fibula from the periosteal sheath authors give a summary of the literature up to date in regard to callus formation. In 10 fracture experiments where the fibulge in the same animal were roken imultaneously one leg having the penos teum removed first and one having the periosteum remaining inta t showed repair in both cases. In the bone from which the periosteum had been removed the callus formation seemed to be greater than in the other but not so far advanced in its development up to 38 days after the experiment A series of experiments where a button wa trephined from the bone subperiosteally and the periosteum sutured back into place again in contrast to a age where the same operation was done but the periosteum was removed, showed that new bone was formed in each instance similarly namely that it seemed to spring from the medullary part

f the bone working toward the surface only in the ase whire the periodeum was not removed the repair was mu h greater in extent. In regard to the fite of small free bone transplants uncovered by periodeum the authors state that sooner or later these pensh.

In regard to intramedullary transplants the authors than that although esteogressis on the part of the recipient bone is simulated yet the ultimate late of the transplant in death. Protocols of the experiments with the appropriate bibliography are given in the original article.

Campbell W. C. General Heliotherapy in the Treatment of Bone and Joint Affections 1 m J Orth S. C. 9 t. v. 9

The author used the sun treatment in % cases in 8 of which subtenet time had not elapsed to obtain results. Of 4 with installe improvement was rapid in 3 but for various retrous exposures could not be continued. Of the remaining, for in with treatment was satisfa title given with resulting the state of

He concludes

r That there is ripid expulsion of sequestra
2 That there is mark third early beneficial effect in severe septimentally and tions.

That there is rapid volution of the tuber rular

4 That there is much difficulty in ha ing the exposures regularly given in well i guiated general

hospitals

5 That close att ntion h uli be given to ortho-

pedic measures for the prevention of the deformity as in any previous triatment by using removable apparatus and extension.

6 That a decided ad an um in has been made not only in the treatment. I urgi all tub rulosus but in certain other affections of bones and joints.

Roberts P. W. The Influence of the Oc Calcis on the Production and Correction of Valgus Deformities of the Foot I is Orth 1ss Washington 9 to Via

In this paper attention is called to the importance of the os calcis as a hast factor in the cause of valcus deformities of the foot and as a medium through which weak foot and moderate paralytic valgus can be controlled. The observations are based upon the prin iple that a body with an arc for its base can support a superimposed weight without tilting only when the thrust of that weight is received over the introf balance. It is shown that the under bearing surfa e of the os calcis is on cross-section of the bone at its point of contact with a plane surface an arc and is therefore subject to the law just cited. It is further demonstrated that because of the firm ligamentous union of the os calcus to the rest of the toot any rotation of the heel bone must alter the strain on the longitudinal ar h raising it if the superior surfa e of the os calcis is rotated outward and d pressing it if n tated inward. Therefore by means of a plate designed for the purpose weak foot and moderate paralytic valgus may be controlled without any prop whatever under the arch The same principl is applied in the surgical treatment of acquired varu.

Lord J P Arthroplasty of the Interphalangeal Joints im J Onk 8 9 6

The author used free fatend taseta from the fascia lata to relie e some cases of till ting its and

some with congenitally contracted and pathologicalby dialocated fingers. He usually employed 400 novocaine locally and a tourniquet. It is necessary to control bleeding thoroughly before transplants are placed and the wound closed.

While his results were somewhat disappointing in the interphalangeal joints of the fingers the majority of the joints were greatly improved, some to the extent that the patients were satisfied because the fingers became mable whereas before they were almost useless.

Free full motion was obtalled in none of the cases. Some joints, with a chronic arthritis, lingering and somewhat painful before operation, became pain less afterward.

Turnovsky G d The Heterogenous Bone-Peg: Its Possibilities and Limitations. Surg G; α 6-Obst 9 6 xm, 6

In view of the present well generalized belief that all bony transplants are ult mately boorbed, the thow was left try steriled transcullary pegs derived from the long bones of cattle. Suffer it time has t yet clapsed to perm to a positive statement regarding the exact interval which must statement regarding the exact interval which must statement regarding the exact interval which must statement regarding the exact interval which must clause show the bone to be slowly absorbing. Clinically the results have, in the main, been good The callus what tending to be excessive has been firm and primary uni n has been obtained in all but one case.

The distinct advantages of the soup-home pegis are (1) they are easily obtainable (1) they can be sawed or chiefed into any length o thickness (2) they are easily terilized (4) they of not be come brittle even after repeated the brittle. The pegis are especially indicated in transverse or slightly obling fractures as well as i fractures of the next of the humers or femur. They are less satisf c tory in markedly oblique fractures or fractures with coronderable militarcizer of the shaft.

Soule, R. E. The Use of th Autogenous Bone-Graft Pin in th Treatment of Painful Flat Foot Paralytic Valgus, etc. T Am. Ords. Ass Washington, 9 6, M

In his paper read before the American Orthopocality Association in Washington in May on Soule gives his observations from experience gathered I his investigations of painful foot disability over an extended period in orthopedic practice and emphasizes the first that in equired deformities of the foot the astragalus is seldom if over displaced latterally From his findings he has applied a new method of treatment to correct def rmity and retieve pain. It disability which is pidically it a very large per centage of the conditions in Circa 33 cases of the condition of the condition of the proposed of the conditions. In circa 33 cases of the condition of the condition of the condition of the proposed of the conditions in the condition of the conditi

he has appl ed arthrodesis of the astragaloscaphoid joint and autogenous bone-graft pinning of these bones with extremely satisf etory results.

The indicati as for this method of operating in

1 Where ther methods have falled to restore the foot t full function, painlessness, and normal contour after reasonabl trials and a relapse toward the original deformity takes place

3 To save as much lirt! a ... e The disadvantages of the dap a ... at in method

- r There will be less than e of u matel, saining the patient's life because there will be list hance of checking infection
- 2 There will be more hance of the patient losing his life at the time f m sho w
- 3 For the amputation to sue eed it will have to be performed as high a or higher in the limit than the second stage of a primary dush amputation.

4 Healing by first in enti-n cannot be expected. (The cases must be seen to appreciate this

5 The nsk of secondar's harm rehave (a very grave danger in these a e i grail increased Since the routine adoption of the flush method the author states that not a in locale has been lost from secondary harmorrhag follo in amputation in the hospital he is onnext all ith. The only death in their hospital from econdary harmorrhage after amputation, during the last months occurred in a case operated on near the front by the flap method. Se ondary harmorrhage or urred dur

ing transit and again after a lmi i nito the him tall of The need for reamputati n for episor hæm orthal maj be expected at a time, hen the pattent is unable to stand furth roperation and often when there is not en u h lmb a adable for an

amputation.

The ad antages of the Lu h me hod are

r Rap dity with minimum hock

2 A plain open surface for dressing which is

f vorable to the subsequent control of secols and which prevents pocketing

s Great diminution in the risk of secondary homorrhage

4. The operation provides the best mechanical relief of gas tension by dividing all the tusices at right angles to the muscle planes.

s. It allows a temporary amoutation to be per formed close to the sate of the injury so that a permanent amoutation can be performed later (when sensis is under control) a little bove the injured ...

In cases associated with fract in the proximal. end of the bone can be and should be left intact (that is not sawed through) and projecting beyond the plane of muscle-section thus minimizing th risks of esteomyelitis and also providing a useful medium () for the pplication of pressure by means of dressing i case of hemorrhage (a practical point of great value) () f moving and fixing the limb and (x) for the polication of extension to the skin.

The flush circular method may be modified, according t carcumstances by singl flap cut f om th damaged area and turned back, thus saving few inches of bone in the final result although this flap is liable to slough owing to anaerobic or

streptococcal infecti n.

The author lays stress in the after trentment of the flapless amoutation. At the secondary opera tion it is important not to open up muscl planes because of the danger of flare-ups The muscles ttached to the bone bould be carefully separated from the perioateum by snippung with seasons until th amount of bone required t be removed has been bared. If the bone is divided without lacer ating the granulation tissue the operation can be done without any local or general eaction. The periosteum should not be stripped back forn th bone otherwise new bone will be th own out in the muscles.

During the interval between the first and second operation th kin should be kept stretched by means of an extension. The second operation can and should be perf rmed before any serious cicatri cial contraction has occurred. In several instances a complet by healed d comf rtable stump has been secured within month of the original amputation LLOYD T BROW

Kelly M F The Flapless Amputation J Sarre 0 6 111. 676

The author strongly dvocates the fl pless method of amputation! () gaseous gangre e () compound comminuted fract re, and (3) mult ple wounds. The a thor ummarizes the dvantages of the method as foll ws () it saves lif () so es length of limb (3) lessens the risk of sec ndary hæmor hage (4) arrests the spread of infection whereas in flap amputati as separs often recurs in the flap and spreads up from there.

The amputation is done as follows The skin and deep fascia are divided usually by a circular incision

After retraction has occurred the muscles are divided at the level of the etracted skin - not too quickly t allow retraction of the I yers then the bone is sawed off flush with the muscles the vessels are secured and erves properly shortened. Retraction is maily ercome by extension once the face of the wound as clean.

The method enables the amoutation to be do e close up to the in olved area and would seem a rati nal procedure unde conditions which exist at th front. F D Dominer

Bryan, C. W. G. The After Treatment of Amou tation Stomps. But M J o 6 L 480.

The author describes an appearatus for making traction on the ski and soft parts after amoutation f either the flap or the flapless variety. It consists f longitudinal strips of tw inch adhesive strapping applied to the amp tatio stump from the iol t bove t about an inch from the edges of the wound and then prol nged bout twelve inches beyond the edge of the stump These strips re attached to an alumin m rang eighteen inches in diameter. This ring is attached by three pieces of cord t ed to t at equal distances from one another the cords passing through pulleys booked to a Balkan splint to which an extra crossbar of wood has been bolted. The free ends of the cord are tied together and the weights are hooked in. For a thigh amputation a weight of bout eight pounds is used, whilf the arm about tive pounds suffices. LIOTO T BROWN

ORTHOPEDICS IN GENERAL

R berts, P W Paralytic Feet. V 1 M J in. 826

The operation proposed applies t practically all forms of paralytic feet where there is instability of the ankl It is neither so radical as complete astragalect my nor so certain as arthrodesis. The mechanical problem presented in cases of instability I the ankle following paralysis is the re striction of anteroposterior moti n at the tibioastragalar joint nd lateral motion between the os calcus and astragalus Control of eithe of these joints without control of the other will yield imper fect results theref ro it is ecessary that both be included n any plan t stabiliz the foot. If movement t the ankle joint is obliterated, there will still be enough anteroposterior motion between the on calcus and the astragalus and between the head of the astrografus and the scaph kit maintain a considerable degree of elasticity in the foot, Hence the operation under consideration aims to efface the astragalotibial foint and t drop the external malleolus down sufficiently to overlap the os calcis, thus blocking lateral motion between this bone and the astragalus. Through a fishhook incision, such as is commonly used for astrarelectomy the astragalus is exposed and dislocated from the mortise formed by the lower end of the tibia and

nbula. The astraights is then remodeled by resect in a the upper half on a line corresponding, to the superior border of the neck, leaving a flat surface. The ties of the bone are timmed to transform the astraights into a rectaingular block. The mortise of the anale is then squared out to be disclosed backward and put up in plaster of Paris. This dressing is removed at the end of two weeks for in specti, not the position of the foot which at that time may be altered if found necessary and another plaster is applied. The patient is allowed to walk on the foot four eeks after the operation and at the end of ten weeks the plaster is removed and the foot our reals for the position and at the end of ten weeks the plaster is removed and the foot our reals for use.

The advantages claimed for the operation are greater stability less likelihood of relapse and a mu h shorter petiod of after-treatment than is necessary with operations now in use

Bauman G I Congenital Club-Foot Cle him.

In discussing the treatment of convenital clubbot Bauman expreses the opinion that no operation not even a rebotomy or lascotomy, should be pert rimed until e ery other method has been tried. The only expenses to this rule are those newlected or relap ed cases tound in older children or adults in which there is a marked rigidity due to bony deformity. Even these cases should receive thorough manipulation before any open operation is pert rei. I Bauman believes that the most perfect re ul. 5 follow those ases in which no open operation has been performed.

ARTRER J DAVIDSON

Painter C. F. Hallux Rigidus B = n M S J

The author ossilers that the chief factor in the etitlors, i hallow rigid is the irritation caused by the jun ti n in the mp and the upper part of the show upon the end of the metatrial bone of the great (see To the frequent maniformed variation in the length; it the tarsal and metatriasal bones the au h rattributes the occurrence (the condition in unitational lase).

The conservative treatment consists in the wearing of the tom male hoes and the temporary use the metal plate to limit motion of the affected rout.

Surmual treatment onsists in the removal of the ridge in the dorsal urface of the metatarsal or in very evere cases the research of the head of the metat r all bone.

M J a 6 L 6on The a the discusses the position of election for

the various foint as follows In the shoulder roj t the arm should be abducted t about s The elbow ab uld be alightly in front of the coronal plane of the body so that when it is t right ngles and the forearm supinated the palm f the ha d is toward the face

As to the cloow joint the majority of men re better off with the tration at oo. In cases in which both elbows are involved, one abould be

fixed 1 80° and the other at 100

In the forearm if the moveme is f pronation and supination are lost the rad us abould be fixed midway between proportion and supenati n.

All injuries of the wrist joint should be treated with the wrist dorsifiered I the hip-joint ankylosis should be encouraged

in a position of very slight abduction with thish

extended and very slight outward rotation.

The knee should be fixed in an extended positi n. In injuries of the ankle the foot sh uld be kept at a right angle with the leg, so that the sole impinges o the ground in a lightly arus rather than a valgus position.

In answer to the question What hould be done with a flail joi to] es says Secure by opera ti an ani vlosis in the most useful position. The only except on is the hip-roint where by means of simple mechanism a very useful limb may be obtained in pite of the foint being flail.

PRILE LEWIS

SURGERY OF THE SPINAL COLUMN AND CORD

Hastin G B. Johnstone, K. L., and Carr A M Bullet Leslon of Cauda Eq Ima J im M Au of hi oo

The patient a man of a8 comple ed of pain in the left lower extremity The pain would jump from the left buttock t the left pooliteal region. whence it would reach the left little toe and sevend over the foot and the oth toes. It would stop for about five or ten min tes and then begin again. He 'ould not sleep nights could not and rest i the daytime, and could not do his work (that of a watchma) but he was abl t walk.

The pain originated it years previously after he had been shot i the back. One attempt t remove the bullet, four hours after he was abor was entirely unsuccessful Foll wing the shooting, the patient immediately becam pa alyzed in both lower extremities. The paralysis was combined with anesthesia a d loss of sphincter co trol A month later cyntics developed which penated fr two years H could t move aroud fr two years and had t be carned all thus tim in a rocker The ymptoms plainly indicated i volve ment of some f the motor and sensory root f the cauda equina that pply the lower limbs with motion and sensation.

A curved inciston was m d from the first lumba t the first sacral spinous process. The spinous processes of the second third and f urth lumbar verte bree were exposed and emoved. The lamings f the same vertebre were removed and the d ra x posed. The dura was split and dissected free from dhesions to the cauda. The bullet was found t the level f the third lumbar vertebra, surrounded by two solid scars. It was carefully dislodged with blunt dissectors and removed. The alightest posable injury to the surrounding therees was ca efully avoided.

The operation was followed by numbress in the

genitals buttocks, bout the anus, and by retention of nrine f about six days. Fou weeks after the operation the wound cleaned up and for about seven weeks, there still was severe pain in the legs, which, hever was gradually disappearing and the potient was getting firmer his feet To months after the ope tion the pain disappeared ntirely the gait becam practically normal, the calf muscles increased i olum one inch, the pain sensatio was found to be normal - but nly the right leg - while in other reas the sensibility showed th same dist rhances as before the operation. No ch ge a found electric indings in the reflexes. or I the muscle nower. The improvement was so m rked that the patient insisted on leaving the hosestal adfit ble to resume work.

LOWARD L CORNELL

Kleinberg, S. Congenital Anterior Curvature of th Spine Jim Min o 6,1

The a thor describes a case of tru-congenital lordons of the spine of associated with any other deformity.

The case is described in some detail as t \\-ray and laborators turbors. His conclusi as are that this was an instance of congenital lordons in which he believes heredity played part and despit the marked lordous there was no album! una

C C UIL TERRITOR

Armour D Gunshot Wounds of th Spin : Their Surgical Aspect, Lancet Lond o 6 crc. 770.

The author divides gunshot wounds of the spine it two classes () those in which there is o interf rence with the function of the spinal cord () those in which there is more o less interference with the f ction of the spinal cord with or without obvious injury t the vertebral column.

Injury to the vertebral column may be followed later by effects of inflammatory products adhesions narrowing of the spinal canal intra or extradural dot etc.

Immediate injury to the cord may be caused by (1) the missile passing through part or the whole of the cord () fractured bone causing compression contusion laceration, or complete division (3) concussion

The author has found the \ ray to have only confirmatory value in localizing bone injury and foreign body position.

The points of importance arising regarding operative intervention are (1) Will any benefit to the patient result from the operation? (2) Will his life be endangered by the operation? (1) Will be be made worse by operation?

The author then discusses indications for opera tion and urges interference under proper surgical skill and asepsis in all cases in which complete section has n t taken place, providing the patient is in a fair general condition. He says. It is unfair It is unfair to the pat ent and unfair to surgery to wait on and on till hope gives place to despair and then call in a surgeon as a last resort to perform the impossible

Operation is therefore indicated (1) to relieve pressur from depressed or displaced fragments of bone (2) to relieve pressure from blood-clot or from extensive hæmorrhage, either extra or intra dural (3) to relieve pressure and prevent further destruction from cedema by enlarging the constricted bony canal (4) to remove the danger of pressure from exudate and inflammatory thickening H. W. MEVIRDING

Collier J Gunshot Wounds and Injuries of the Spinal Cord La c + Lond 960 7

Eighteen months service has given the author an excellent opportunity to study gunshot wounds and injuries to the spinal cord The nature of lesions caused by high velocity bullets shrapnel fragments of shell casing and by the concussion of high explosi es without any external wound are 1 Direct lesions—missile through cord

Indirect lesions (a) those du to an in-driving of bone etc into the spinal canal (b) impact lesions where the missile strikes against the bony wall f the pinal canal () concussion lesions from the shock of high explosives

3 Secondary lesions perithecal and intrathecal hæmorrhage medullars hæmorrhage and throm bosis m ningitis cedema (may com late and cause in rea d ymptoms)

4 Rem t lesions which may be found anywhere in the pinal cord and hielly near the surface spot of necros sieve like rarefaction pun tiform ham trhages ordema, swelling of arons result from pa sage of a missile through the cord or from n us ion suddenly raising pressure

Case hi ton a illustrating the above lesion are cited Lapecially interesting are those resulting from concussion and to shell bursting near the natient without external wound yet producing severe local transverse lesions of the cord

Root lesions are produced by projectiles directly or indirectly the latter from subperiostcal harm orrhage periostcal swelling or pachymeningeal hæmorrhage

Intrathecal hæmorrhage is discussed and the difficulty of explaining the physical signs unless this condition is borne in mind 1 shown by case history

A case is cited of total necrosus of the listal segment of the spinal cord at autopsy in a case without sign of hamorrhage or septi prices three munth after injury which had produced a total transverse lesion at the third dorsal segment

The author discusses reflex actions contra tures disturbances of sensibility and the distinction between root lesions and central 1-sions and prognostic indications H W MEY EDING

Hull A J: Treatment of Gunshot Wounds of the Spine. Bu M J g f

To be successful spinal operations must be per formed at an early stage before any vital changes have occurred in the cord By d laying operative interference cases lose that chance f recovery either by the sepsis spreading or by pressure on the nerve tissue causing these vital changes to take place

It would appear justifiable to operate upon spinal injuries when the X ray localization shows a foreign body present in an ac essil le position, an l'especial ly when there is eviden e of some remaining con ductivity of the cord as here the removal of pres sure may be followed by great imprement. Pain in some spinal lesions is so intense that an operation is justimable whatev if the lesion of the cord

Three lines of treatment are indicated (1) pre vention of senses. (2) removal | f gross pressure upon the spine and (3) the prevention f complications which threaten life R B COTTELD

Sayre, R H The Occurrence of Late Rickets. 4m Orth 1 Wash gt 0 6 M v

Rickets occurring in adol-scents and adults is less uncommon than has been supposed. Its occurrence abroad has been much more frequently noticed than in the country Appar ntly nekets in the adolescent is frequently of the recrudescent variety and in a number of the author's cases the patients have been subjected to various operations for the relief of the deformity earlier in life but no effort having been made to eliminate the under lying cause of the softening of the bones the deformities had recurred or else deformities of an equally disabling character had taken their place requiring further operative intervent on

In one case a gil 10 years of ge who had had four pr vious operations before coming und r observation the femora were so soft that the osteot me cut through at the first blow when a supra condyloid operation was done but six months later after the patient had been fed upon phorphorna and cod-liver oil, the edge of the chasel was broken off off while an operation was being performed upon the shaft of the femur to correct twist there and a second instrument was used to complete the operation.

In the case of a boy by ears of age, marked knock had developed in the space of three months, and reasoning that if the bones were sufficiently soft to create so ma ked a deformity in on short a time, pressure could correct the position, the legs were put in plaster-of Paris bandages, which were robsequently sawed through at the point of deformity and wedged straight, a perfect result being secured without the necessity of breaking the bones. This boy was placed on phosphorus and cod-diver oil, and remained straight. These cases emphasize the necessity of attending to the underlying cause

producing the softness of the bones as well as merely correcting the deformity

Shackleton W.E. Som of the Surgical Aspects of Painful Back. J. Am. M. Au. 9 6 kvs. 600.

Shackleton describes an anatomic variation of the transverse process of the fifth I mbar vertebra the lumbar rib and he cites three unmistakable cases, two of which when operated upon were entirely relleved. The condition arises in middle adult lif after years of hard labor but may also follow fracture, or some infection. The backache seems to be d to impingement of the process on the flium sometimes thus separating the sacro-illac joint, or to impingement on the nerve itself. The fifth humbar nerve seems to be the branch most commonly affected, causing most marked motor symptoms in th peroneal erve. In the two cases reported the prol nged processes were removed and instant relief occurred R. G. P. CRAED.

SURGERY OF THE NERVOUS SYSTEM

Bucholz, C. H. Partial Resection of the M tor Nerves in Spastic Paralysis. T. Am. Ords Ass Washington, 9 6 May

In spastic paralysis the restoration of the function of the paralyzed limbs demands. long continued re-education and exercise treatment. A greatly defective balance and actual contract re-may mak rational exercise difficult if not impossible and may require surgical interference.

Until recently operations on the tendoms and muscles were practically the only operative procedures in use in these cases but within the last two years operations in the nervous system directly has e been done in various ways. Among these operations may be mentioned the following

Resection f the posterio roots of the spinal cord (Foorster's operatio)

a Operations to cause temporary paralysis by the injection of lcobol into the nerv -trunks (Al-

lison a method)

3. Partial resection of the motor nerves (frequently called Stoffel's operation)

Although the last-mentioned method has at times been used it was through Stoffel automical studies and clinical work that the method has been so thoroughly developed. Stoffel has shown that in the cross-section of the nerve trunk the arrangement of the single bundler is practically the same in every person, so that anyone familiar with the anatomy of the cross-section will find without difficulty at a given place that bandl for which he is looking

Stoffel's operation consists in a partial resection of the motor supply of the apastic muscles either after the motor branches have left the main trunk, or within the main trunk fuelf. The latter method is used only when the former is rendered difficult or impossible by the anatomical conditions.

Stoffel's operatio is in the author opinion i dicated n all cases of rather localized spasm with markedly defective balance which is of showing any mortwerpent and ex reuse treatment.

The ntra indications e as follows

The progressive haracter of the disease caus-

The progress ing the spost city

treatment

Permanent contracture in which case the contractures should be eliminated first and partial exection f th motor upply may be done later after ufficiently l ng int rval, if a markedly defective balance persists after exercise treatment.

3 Marked prevale ce f the parentic element.

A Mental deficiency or youth of the patient which pre ents carel datter-treatm to by exercise. Just as to the resect! I the poster! roos it has been mad an axiom by Foenter himself that developmental and educational exercise treatment is the most important port of the whole treatment, which is only to be made possible or easier by the operation, so too before doing Stoffle so operat on on must be sure that an opportunity will be afforded to give the patient a sufficiently long careful after

The technique of the operall in is briefly described for partial resection of the motor supply of the triceps cruris and the pronator muscles of the forearm. A modification of Studies operation by the author constituing in transplanting some of the motor supply of the triceps into the personnal nerve is briefly described.

The two cases reported by the author were selected from a series of 36 cases of complete zerve sections which were operated upon. These were the only cases which the author has been able to follow

The first case was a resection and suture of the internal populteal sciatic on the right. The op-

eration was done in January 1915 four months after the injury and voluntary motility was effective four months later

In the second case there was a complete section of the radial nerve which was sutured in February 1915. Voluntary movements in this case were not noticeable till ten months later.

In the first case the injury had not caused a total anatomic section of the nerve but the presence of a voluminous neuroma necessitated resection

In both cases there was complete restoration of the electric functions of the nerves

II A BRENNIN

MISCELLANEOUS

CLINICAL ENTITIES - TUMORS ULCERS ABSCESSES ETC

Lambert R A. Tissue Cultures in the Investign tion of Cancer J Ca cer Research 19 6 1 160.

A review is given of the results which have been obtained with tissue cultures in studies upon cancer and related subjects. The technique is described and emphasis is laid on the fact that the tempera ture of the culture medium and the tissue does not have to be needly controlled while the cultures are being made moreover some time can elapse between the taking of the tissue specimen from the body and its immersion in the plasma medium in which it is to grow There has been very little trouble from bacterial contamination, probably because of the fact that serum has a bactericidal property of itself The principle in general consists in placing small pieces of tissue o 5 to 2 mm in diameter in plasma derived from the blood of the same animal making the whole a hanging drop preparation and scaling it with vaseline

Sarcoma and connective tissue cells are wont to wander out singly or in chains, while epithelial cells normal or neoplastic, tend to spread in sheets or groups The cancer-cell, especially the sarcoma cell, tends to show a greater motility as compared with the corresponding normal element Sarcoma cells may often be seen traveling through the medium at a rate equal to that of a polymorphonuclear leucocyte This fact probably throws light on the mechanism of the invasive growth and spread of cancer in the body The author calculates that a cancer-cell by means of this locomotion might in four weeks make its way to the axillary fossa Con tinued propagation of normal cells especially those of connective tissue is as a rule much easier than in cases of tumor-cells Many carcanomata and sarcomata are very difficult to propagate even in pri mary cultures, while others quickly die when transferred early into fresh plasma. On the other hand connective tissue becomes much more active in subcultures Tumor-cells are much more susceptible to heat that is it kills them mu h more quickly than it does active tissue cells

The author quotes Lambert and Hanes who found that rat sarcomata cells will grow quite as well in the plasma of an immune rat as in the plasma of a normal rat without immunity. This observation affords further evidence that cancer immunity is not to be attributed to circulated antibodies of a cytotoxic nature. They are further able to show that an animal of foreign species particularly a rabbit may give plasma satisfactory for the growth of tissue elements derived from an alien species The plasma of an animal that has been immunized to either the tissue or the blood of another is unsuitable as a medium of growth for the cells of the animal which supplies the immunizing substance In other words it is distinctly toxic for these cells. The author emphasizes the fact that variations in growth of preparations occur from the factor of the depth of the hanging drop and the density of the fibrin meshwork. These two factors influence the extent to which the active motile cells wander out The author cites an instance where an extract of human tumor appeared to inhibit rather than to stimulate the growth of normal human cells.

He has been disappointed in stimulating tissue cultures by using Scharlack R and Sudan III He thinks however that in spite of the fact that possibly with the exception of increased temperature there has been little found that will stimulate tissue growth, this is a most important and interest ing field of investigation in regard to the cancer problem. If G Stoan

Calkins, G. N.: The Effects of Cancer Tissue and of Normal Epithelium on the Vitality of Protozoa; Didinium Nasutum J. Ca. cer. Retect. 9.6 i. 205

In experimental study the author used didinium nasutum which lives on protozoa and will not est bacteria, so that he was able to control the factor of putrefaction to a certain extent in the food given them to live on The carcinomata he used were derived from tumors inoculated into mice, at vary ing intervals, so that when needed they were of th same are and approximately of the same size The tumor was fed to the didlnin in definite tated amounts in addition t their normal food supply of paranecia. Two series of controls were run. All the didinia were derived from the same tock. The treatment was given in three periods of five days each, from Monday to Friday inclusive. The living indicators of the didinia were observed for varying periods fter such treatment and compared with the normal controls, attenti being especially paid to their rate of multiplication and theil death. Identical experiments were conducted, only that normal enithellum from the mouse was substit ted for the cancer tessu in feeding The dosage of food was accurately gauged. All

tissue fed was finely minced and given fresh. Is The conclusions drawn from the cancer feeding were () cancer tissue contains something which produces a depressant effect didinium () it also produces something which produces a stimulating effect. In weak doses the stimulating f ctor f cancer tissue is apparently more noticeable than the detremine effect, o lethal. Larger doses than usual were fatal through all the regardsms. In feeding normal enithelium the a thor found there was no depressant lethal f ctor in it but that I caused a stimulation f the organisms. The double dose with cancer feeding gave mortality of 4 per cent or more than twice that of the control 5 per cent while the double dose with epithelium ga e a mortality of 6 6 per cent against 10 6 per cent f the control. With four times as much tissue material in the double dose series as in the half dose, the death-rate with normal epithelium was not raised even to that of the normal controls hence the lethal factor cannot be due to an exhaustion from the excess of the stimulating f ctor

The autho then proposes a theory for the origin of cancer namely, that cancerous changes may originate in cells from the prodominance of the stimulating factor. This, be thinks, may be caused by the autolysis of cells which are being constantly destroyed at the seat of any chronic intration. H quotes Bullock and Rohdenburg, working in his laboratory who showed that in rate that had the posterior lobes of their pancreas closely ligated and allowed to remain and autolyze. It he adja cent parts of the pancreas showed greatly increased mytosis.

Bell, E. T. and Henrici A. T. Renal Tumors in the Rabbit J Cancer Research 9 6 i 57

Bell and Henrich telleve that new-growths of any lit of any very tree in relibits. Although the street of the street of the street of the process, reports of only 55 to more were found. Of the recorded tumors 44 were terme and a were tumors of the kidney. The authors two meoplasma occurred in adult male rabbits both having been found on the same sitemoon, and although they state that they have autoosled over 400 rabbits during the last three years, no ther tumors have been seen. It was impossible t ascertain the ages of the rabbits or whether or not they were both from the same litter since nimals obtained from different persons had been put t care together In the hist case pherical t mor _1 cm, in dlame ter was found about the center of the outer border f th left kilney. Apparently it was of cortical origin since it did not i alve the medulla. It was harply marked if from the renal tissue fairly firm, and whitish gray in color A thin prolongation f enal capsul covered the tumor No metas-tases were fou d. The second case was very similar to the first though pparently in a much later stage of development. There were a f w small areas that closely resembled the structure of the first tumor but almost everywhere the cellular masses characteris-

cords and tubules

These rabbit tumors thus correspond closely with those neoplasms of the binan kidney commonly described as adenoasroomats. The simplest interpretation of their right is to regard them as baving developed from portions of the met nephrogenous than which became enclosed in the kidney during its early development but failled to form connections with the collecting times. Since in striated mixed was present they are not comparable, the uthors taste to the nulred tum is of the kidney which occur so frequently in children, and which are best explained as derived from portions of the piratitive segments.

Grosse E. Bernay

tic of the first tumor had differentiated into solid

Tysser E. E. Tumor immunity J Ca cer Renerch 0 6 i. 5.

In a consideration of tumor immunity it appeared to the other of earthle to discuss resistance to spont news terms and to implanted tumor appeared by Although results obtained with experimentally implanted tumors have contributed to the biology of temors, these results cannot be ppl ed directly to appearance to temors, these results cannot be ppl ed directly of temors, these results cannot be ppl ed directly of the contribution of the post annous tumors of this is especially true with respect t immunity. It has long been recognized that immunity to implanted tumor gives no assurance gainst the subsequent development of spontaneous tumors.

The results f the experimental investigation of tumors, as well as of clinical and pathological beer vail n, appear to f vor the following conception of the nature of t mors and their relationship to the other thance.

The interreactions of the normal tissues are mutually beneficial so that their relationship is one of symbiosis

The anomalies and benign growths, while not distinctly harmful are usually of no benefit to the individual the relationship is one of commencation.

The malignant t more are in many respects parasitic in nature, especially since they develop at the expense of the other tissues of the body. They are so adapted for growth, once they have become established that they seldom arouse any effective result ance on the part of the body. There is some evidence however of a local reaction of tissues unfavorable to the growth of many different types of tumors.

Immunity to transplanted tumor is based on foreigness or incompatibility of tumor and host This holds true whether the tumor or the animal is taken as the constant factor with which to test the other. Although the legree of foreigness is not sufficient for the production of markedly cytotomic or cytolytic sent as when different species are employed it appears probable that an immune body is formed with h in the presence of the antigen—or living tumor—excites an inflammatory reaction in the tissue around the tumor so that the latter is solated and eventually destroyed.

Both sus 'publity and non susceptibility or the ability to acquire immunity are inherited not as a singli unit fa for but apparently as a complex of men leliang factors. Yon-ausceptibility and susceptibility are apparently based on factor differences or in other words in unlikeness or foreigness. Non susceptibility may thus depend with one tumor on a difference with respect to mew factors and with another tumor on a difference with respect to many factors. In the omparison of a stock of Japanese walliting and several stocks of common mile the non-susceptibility of the latter to a carcinoma Jiw A is based on a difference with respect to a large number—probably welve to fourteen—of independently inherited factors.

Susceptibility is in this material a dominant character since it is manufested when its factors are present in a single representation as in the F r hybril. The present of a single representation of the factors of non susceptibility in the F r hybrid apparently stimulates the growth of the tumor for its rate of growth is more rapid than in the Japanese waltring mouse in which the factors of susceptibility are doubly represented.

There are marked differences in the behavior of vari is tumor on transplantation in given classes of mice. Even tumors arising in homogeneous races show such inferences and this may be attributed to the acquisition of new characteristics by the soma which are manifested in the development of the tumor. The tumor since it breeds true with respect to these characteristics in the course of art halp reputation may be regarded as a modification of the tumor. The tumor of tumor of tumor of the tumor of the tumor of

Simon C. Cure of a Suppurated Chancrous Bubo in Light Day With ut Apparent Clearity by Filliform Drainage (* 1860 1 b bon hancrel 1 pour en h t jour 1 to 1 d ce thiorm) B B I to m Soc and d hop d P 0 5 i 38

Simon reports a case which ten days after recovery too soft hance showed ulceration of the glans and a lift inguinal adentits. Miter about twenty

days treatment by pun ture etc with hitl effect fillform (thread) drainings of the bulbo was instituted Immediate improvem ht was of served and in eight days the skin hal a normal appearance

The author ha tens to report the ase in which he thinks the method fultion framage it us formed a long and wearismed discuss into a light allment because he thinks that the prizedure is of distinct therapeutic value in the trainment of bubb.

The author having observed the guagement of a diabetal presence or absence of hime the citizen in the unner he undertook a consideration of the influence of authors of a sense of cases. The report is based on a study of 138 consecutive major perative asset. Except in a few energency cases in his flucose and so dat adops was a given as a short time before the operation the following is committed.

Soda bicarbonate 3 ss in one half glass—ater T i d. one half hour before meals—was given for two days preceding operation

Soda bicarbonate and glucose aa 7 ss with water q a. ad 5 vm was given as at tention enema, B i d. for two days preceding operation. Lequid diet and large quantities of water in the given for 48 hours preceding operation but no buttermilk or egg albumens for 14 hours preceding operation.

Castor oil 35s was given the morning preceding the day of operation Soap suds on mata were used the night preceding and the morning of the operation

Strontium bromide gr xxx was given the night preceding operation to insure a good night s rest. Morphia gr 1/8 with scopolamine gr 1 100 was given one hour preceding gas and oth r anaesthetic.

After operation the patt it were again given sold bicarbonate 53s in one half glass of water one half hour after meals for se erul days. Water and liquid diet were given as yoon as nausea ceased and continued until a light det was given on the fourth day. In climnamt was given on the third day after the operation.

There was no mortality in the ent re series and only five cases of a preci ble shock. This has led

the author t believe that acidosis has a dominating influence in surgery and that by careful pre and post-operative treatment it may be largely eliminated. From this series, he believes that post operative nauses a greatly diminated by the preliminary use f sods blearbonate. Garrawoo

SERA, VACCINES, AND FERMENTS

Sellarda, A. W., and Minot G. R. Th. Antagonistic Action of Negati. Sera upon the Wassermann Reaction. J. Med. Research, 9, 6 xxxl. 3

At the time when the Wassermann react! was a mechanism first an gursted it was assumed that is mechanism was complet by understood i.e. that it conformed precisely t. the B. det.-fengou phenomenon of compl ment fization. With the demonstrat in that peculia cant gen was not only unnecessary but that it was inferio t. som of the non-specific antigen, is became evident to once that complement fization as policed to the diagnosis of syphilis connot be explained the hasis of the pile men of Bord t and Gengou. Not only is the reaction non-pecific but t is now well est blished that the Wassermann reaction may sometimes occur in certain condition so other than syphilis.

Investigation as t whether must seen are thely negative, in this enter that they would intagonize a positive serum forms the base of this paper. These findings are considered in regard to their practical bearing upon the Wassermann reaction and upon the method of complement fixet on a general

A simpl method was adopted in order t test the effect of negative seru pon a point e syphilitie serum. A small amount of negative serum was mixed with the midmal amount of positive serum was mixed with the midmal amount of positive serum that would cause complete fixation. A Wassermann reaction was dooe of this mixture in the usual routiness of the mixed of the service of the continue of the con

certain special cases.

2 The extent of this inhibitory ction in news.

tive sera varies widely in different diseases but it is usually comparatively weak. It is easily demonstrable even though it is present only in slight degree. 3. Human sera present three distinct phases in

3 Human sera present three distinct phases in their behavior toward the complement fixation of the Wassermann reaction () negative (2) positive

and (3) inert action.

These emits are explained most readily on the bards of a balanced mechanism. The inhibitory action of negative sera cannot be accounted for solely o the basis of its content in natural sheep amboceptor Gzonoz E. Berns

Smith N R. Th Serotoxin of Jobling. J Lab 5-Cl s. Med 9 6, 1, 584.

The production of a serotoxin by treating homologous and beterologous sera with chloroform and

ether as reported by J bling has found wide accept anner among workers in the field of anaphylatorina and is incorporated in the literat re of the subject slongsids the cartler pie ere w k of Richer Bordet, Friedberger N than, od others Jobling maintains that the ferment ct or of the serum is held in abrevance maily by an unsaturated lipoidal ant tryptic substance with the mail of which by lipoid solvents permits the base of the mail of which is not serum proteins, some work was under w in bis laboratory in which has platting of germ betamee by sera was the desured end.

I the light of Jobling a work it seemed to the the reasonabl t assume that the splitting ct n of th sers could be greatly acreased and accelerated by shaking ut the sera with chloroform before neubati with the germ substance. Therefore rabbit serum was shak with on tenth its volume of chi rol rm four mn tes. th f ged t 8 000 R P M f te m te and the supernatant serum carefully pipetted off from a precipit te that upon ce trif gat was inter posed between the chloroform the bottom and the scrum above. As a matter f routine co trols were mad by testing the ction f th serum on guines. nurs before neubation with thi germ substance As high as o com of the normal untreated serum had been i jected without effect, but since the M L.D of serum and germ substance after incubation was known by trial to be 3 ccm or less, the control injection of the n rmal serum was usually limited s ccm. But upon the injecti n f the chloroformed serum in 3 cm quantities as a control, that is, without incubation with germ a batance, the plan died instantly Reduction of the dose to one cubic centimeter still produced death i most cases, and alw ye a marked prostration.

The character of the deaths, together with the utopsy findings, clearly indicated typical anaphy laxis and pointed strongly to the residual chlorof rm in the serum as the toxic agent.

Smith concludes that the intravenous injection of high dilutions of chloroform may cause usublen death in guines pigs and that when blood serum has been takken with chloroform the complete removal of the chloroform is difficult. The toxicity of the serum isla with the completeness of the removal of the chloroform. Death in guines pigs caused by the intravenous injection of serum which has been shaken with chloroform is often at less than the contravenous properties of the contravenous contravenous contravenous when the whom when the contravenous

Hektoen, L. Vaccin Treatment. J Am M Am

The general results so far from the routine use of commercial vaccines polyvalent and mixed, have no val e as evidence f r against curative useful ness of vaccine treatment and hence no value either with respect to the soundness of the theory, on which vaccine treatment primarily has been developed

In subacute and chronic localized infections the results appear to indicate that specific vaccines properly and skillfully used have value quite likely because they increase the production of specific antibodies as demanded by the theory but probably also because they stimulate leucocytic and other activities.

In typhoid fever and possibly also in other infectious diseases the intravenous injection of specific vaccines and also of other substances may induce crisis and prompt recover. The mechanism of his action is not fully understood but as it involves something more than or literent from, specific stimulation of the production. I fantibodies it cannot be interpreted in terms of the current conception of the a tion of vaccines. We are entering therefore upon a new and interesting development in the study and treatment of intertious diseases.

Della Valle, L.: Suppurative Hæmatoma of the lilac Fossa (I matom ppurati della fossa lilaca)

Riem m d 0 0 0 00

The author says that while almost every variety of memotions has been the object of very close study and detailed description deep hematomata of the line fossa do not get the amount of attention which their importance demands particularly on account of their complications in suppurstions. His article is therefore devoted to a detailed description of the pathologic anatomy symptoms, diagnosis and treatment of this condition.

His study is based on clinical data obtained in hospital cases observed and operated upon by him within the past few years

In the treatment of these suppurative hems tomats it must be noted that the pus forms a was subpersioned focus which is limited in front by the fascia illians and beneath by the crural areade. To open this therefore the incision must be horizontal and above the arrade in a point indicated by the illicuation while a voiding the epigastric artery. The skin subcutaneous fascia, the aponeurosis of the oblique muscle the transverse and the fascia transversalis must be cut through before the pus focus is reached. A hematoms of large dimensions may more conveniently be evacuated by a lumbar in thio.

W. A. Beenview.

Kleiner I S The Disappearance of Dextrose from the Blood After Intravenous Injection I Exp M d = 9 0 Ndn 5

The chief purpose of the author's present work was to study the disappearance of sugar from the blood under vanous conditions. In order to obtain a basis of comparison a sense of experiments

was first carried out in which devtrose was injected into normal animals. These experiments brought up the question as to whether the passage of sugar from the blood into the tissues was a vital process and led to a series of experiments in which dextrose was injected into dead animals. These experiments vided the following results.

I As has been found by other investigators when a large amount of lythose is injected in travenously into a normal dog it is pears from the circulating blood in about no minut—after the end of the injection—Varying amount—an average of 60 per cent—are cy rt I in the unne

Even in nephrectomized animals the same quantity will leave the ir ulati n in the same length of time as in normal animals.

This phen m n n so ms to be at least to a great extent independent of vital processes since dextrose after intravious maje from into dead animals us found to I ave the Hood rapidly

4. The phenomenon is in lependent of the important abdomnal organs for it also occur in animals (hiving or deal) in which the aorta and infenor vena casa have been ligated near the diaphragm thus abolishing most if the circulation posterior to the hiphragm.

5 The fact that a on ilcrable amount of the sugar passes from the cr ulation into the surround ing tissues was established by inding an increase in the carbohydrates of the muscle tissue. This was done in the case of the living anterior animals and in the whole of anterior dead animals. In most of these experiments there was also evidence of the formation of polysaccharides in the muscle tissue.

Willmoth A. D. Some of the Uses and Abuses of Normal Saline Solution 4m J S g 0 6 xxx 147

The author reviews the history of transfusion with its many difficulties and uncertainties dating as far back as 1492 when Pope Innocent VIII was given intravenous transfusion of blood the donors being three boys. This effort was like many subsequently unsuccessful and not until the middle of the seventeenth century did transfusion become a recognized surgical procedure. In 1666 Lower wrote the first detailed account of transfusion followed soon afterward by Denys of France with three successful cases. It being little more than a curlous experiment after several unsuccessful efforts it was abandoned until the mineteenth century.

An attempt was made to overcome unfa orable results by using something that would supply the volume of blood yet be easier to obtain and safer to administer from a surgical vice-point and would subject the patient to no danger of disease ensisting in the donor. Milk and oth r albuminous fluids were tired and soon abandoned.

Isolated cases occurred earlier but Schwartz in 1881 gave the first methodical description of saline infusion, this being the first reliable information concerning the use of fluid to take in place of blood. Since more has been learned of the vari us constituents of the blood, ther inorganic salas such as potassium and calcium, were added to the sodium to chloride sodiution. Runger and Lockes soluti ns, whose special gravity should be only being most concerned.

The fact that sodium chloride is found in liberal qua titles in most of ou food possibly econ is for its induscemblants use in surgery. It is changed by lactic acid int sodi in lact t thereby settl g free bydroghlome and It is commonly believed that the kidney glooneruli have o limitations for excreting

water and the chlorides.

The question of the use of salt solution has not

(5) its use i sepsis.

"Sait sol it n'may be used the following a ya (i) intravenously especially after ampustal and before tyring the vessels, () intra-arteri lly (3) by hypodermoclysis, (a) by proctocysis, (3) by leaving a quantity in the belomen after cellotomy. It should be used at a temperature of o to so F. This temperature is perfectly safe, since gl bullin coagulates: §§§ F and serum albumna at 6. F. and experimentally 6; F. has been well borne by the dog. The best acts as stimulant to both heart and blood- casels, a point t. be remembered by the obst trican.

For the relief if shock it should be used in small quantities by the intravenous method t tempera ture of 20°F free ently repeated, rather than a one o more large injections, thereby overwhelming the heart. The conditions to be met are in striking contrast to those resulting from hem orrhage where death res it from absol t loss of blood, not enough remaining in the vessels to ustain vital functions even though it could be kept in active direulation and death results from mechanical interference not enough blood remaining i the vessels to enable the heart and elastic arteries to transmit the f ree of the heart co tractions to distant portions of the body. As conseq ence the blood fails to complet the circuit and all centers suffe from ansemia carned to the point of death. Experiments have shown this would not occur. even though one-half or two-thirds f the total vol me of blood be lost provided the circulatio be maintained by supplying fluid in place of blood.

In the preparation and use of saline in any case, much depends pon the strength and composition of the solution also the technique of its dministration. Too little salt causes the corpuscies to swell and lose their hemorobian, or completely destroys them too much causes them to shrink. To insure correctness tablets should be used or stock solution kept that has been prepared by actual weight. This solution should be prepared by sterilizing by fraction at methods.

In pny te homes water from the teakettle is sterile enough for practical purposes to this add a heaping tea poonful of salt and four drachims of gl cose to the quart, this bel g accurate ugh

green to the quarter and to a monuture. jections thrombin is indirective
5. Chronic localized infections f demonstrabl
etiology not amenable to other treatment. Im
munized blood should of course be used in these

No blood transfusion should be undertaken with

out first making agglutination or hæmolysis tests of the patient's and donor's blood

LUCIAN H LANDRY

Minot, G. R.: Methods of Testing Donors for Transfusion of Blood. B. i. M. S. J. 916

The author rea hes the following conclusions after a full discussion of the subject

A donor f r transtusion of blood sh uld not only be healthy but should belong to the same isoaggluination group as the recipient

Simple and quick methods for testing this have been described. What these tests show in rit or can be taken as reliable evidence as to what may happen in rito so far as agglutination and hæmoly has are concerned.

Even when donor and patient belong to the same iso-agglutination group there may occur however after transfusion, reactions of unknown nature which are probably of not so severe or serious a nature as hemolysis

Agglutantion often dies not oc ut in the and it does it does not always cause a severe reaction because of the following three factors: (1) interference with agglutination by an ex-ess of non agglutinable cells: () absorption of the agglutinan by the agglutinable cells (3) the degree of concentration of the agglutinan

Hæmulysis does not always octur in orro when donor and recipi nt belong to different iso-agglu tination groups because only about 20 per cent of sera that are agglutinative are hem lytic. Hamoly sis however never occurs without beling preceded by or associated with agglutinati n

If hamolysus are present in the plasma of the donor or recipient or both hemolysis may not occur or may cause but a slight reaction nerico occur or may cause but a slight reaction nerico because of the following factors and their quantitative relation to each other (1) concentration of the hemolysus and a certain degree of absorption of the hemolysus by the hem

Singleton A O A Reliable Method of Blood Transfusion S /k M J Offi Ato

Singleton reports a method of transfusion successfully used in ten cases

His apparatus consists of a graduated glass container with the bottom drawn out into two cannulalike processes for connection with the vens and with the top conne ted by a rubber tube with a pair of pressure bottles

The container is stenlized, dried and coated with parafin and connected with the veins of the donor and the recipient respectively following the usual technique except that the veins are flushed out with citrate solution prior to the insertion of the cannular

About 50 cm of a r per cent sodium utrate solution is poured into the namer a tourniquet is tightened around the d n r arm and th clamp is removed from his vin. The produce bottle is immediately lowered by an as i tant in fucing a negative pressure in the ontain r and the blood rushes in. The am unr obtained depends upon the rapidity fits flow the low rihe fithe small r is the amount till i brun i bully al ut Having secured 200 c m can be htainelat a ti 1 this amount in the rtain rine pro ur bettle is immediately raised and the black tred into the recipient's vein the vein of the 1 nor 1 ing ries ed between the thumb r l nager and the lamr r moved from the recipi nt in At ut of con should be left in the at in r and the proc as repeated. It is essential t kay the blood in ving

Although this method is not emple it an Ference upon to transitise into quirting the label ides sired with perfect sales or the paint not fit the author hinds that it goes a produce that it more uniform and more easils introduced by the use it a viring.

Of the to make it instituted over it is pellingra, 2 for permicious anamina a to rip un period segis it for permicious malana and a tir harm rich ge. The three cases it harmorth ge should be the proposed and were cured the a et permition malana showed marked improvement the other cases ided to one of the cases it permicious and mua an unrelated pers in was the domining that transfusion. On the see in law tilling this transfusion the patient level ped at imperature of ror with persisted for seit allay and he suffered some alight harmorrhage it in the now.

The author emphasizes the importance of making, Wassermann, hemolytic and agglutum tests with the blood of the lonor pre-nous to the transition, but regards the blood of an immediate relative as perfectly compatible in the greater per entage of cases.

Peterson E. W. Results from Blood Transfusion in the Treatment of Severe Post homorrhagic Ansemia and the Hemorrhagic Diseases J. M. M. int. 9 0 1 9

Peterson studied the routes of blood transfusion in severe harmorrhagi amemia and the harmor rhagic diseases. His conclusions hased on the literature and a series of nine cases reported in detail are as follows.

Transfusion of blood in ramus ular injections of whole blood and intrav nous and sufficient must enhant measures and are of value in the most eith rent measures and are of value in the order named in the treatment of hemorrhage and the hemorrhage diseases.

In severe cases of acute post-harmorrhagic anamins, blood transitusion is the best a 3 t times the only efficient means of resuent ting a dving patient. In chronic post hiemorrhagi namina provided the cause of the bleeding is removed or

remedied no other measures will compare in efficiency with transfused blood in producing hierastopoletic stimulation.

In pathologic hemorrhage, transitution of blood has on numerous occasions proved effective after the failure of all other measures. It should be resorted to then, in those cases which do not respond promptly to the simpler methods of treat ment.

A. Emporture.

Barnes, F. R.; and Slocum, M. A. Direct Blood Transfusion with the Kimpton Brown Tubes. 4 m. J. H. Sc. 0 6 ch, 727

Of the 9 cases reported by the authors 8 suffered from hemorrhage and were practically moribund when transfused the other suffered from sepsis One of the cases of hemorrhage was complicated by peritonitis and another by a large carcinomatous mass at the bead of th pancreas

The only difficulty experienced in the use of the kimpton-Brown tubes was in keeping the stoppers in when pressure was applied to force the blood into the recipient even. This difficulty was avoided after the first transfusions by pressing the pain of the glovel hand firmly septiant the top of the tube was a supersymmetric transfusion of the state of the warded altography. With this technique the tubes roved entirely satisfactory.

Six of the patients showed immediate and marked improvement in the general condition and as indicated by the increase in the haemoglobin estimation and in the red-cell count after the transfersion. The patients who died were those suffering from sepsis and one suffering from carenoms.

The authors were impressed by the value and simplicity of the Kimpton Brown method of transfusion. They emphasize the value of transfusion in all cases suffering from grave anomia, particularly that due to hemorrhage but consider it furfile in cases of scotis.

They found it best to have the donor and recipient so far part that neither would in any way disturb the other nor interfere with work upon the other I W Trance.

BLOOD AND LYMPH VESSELS

Morton, C. A. An Unusual Form of Gunsh & Arteriorenous Ancurism in Which the Soc was Situated on the Side Opposite to th Vein. Lance Load o 6 CR, 537

In the ordinary form of atterforenous aneuthan the aneutimud ase lies between the artery and win and the communication between the artery and win is through the sac. In the case which is now recorded there was a communication between the artery and win, due to the passage of a piece or projectile through them, and on the side of the artery opposite to the communication, where the portion of projectile had passed out of the artery was an aneurismal sac. Where the portion of projectile had penetrated the vrie—t.e., in the side of the vrian farthest from the artery—was what may be called a venous ancurism i.e. a cavity in the tissues containing old blood-clot, communicating with the vein. The piece of metal evidently passed through the vein and artery from below unward.

This is a very rare type of arteriovenous aneurism, there being only one similar case in the series of so gunshot aneurisms reported in the British Journal of Surveys of October 0 5 [H. Seitzs.

Fuller E. B. Notes on a Case of Aneurism of the Dorsalis Pedis Artery So African M Rec. 9 6, xt 35

A male, aged so complained of a painful welling on the back of his left foot, which had appeared a month previous and gradually increased in size.

He denied any history of injury to the foot.

On the back of the left foot just below the annular ligament in the line of the dorsals pedis artery was pulsating swelling about the size of small hen s

egg. The kin over the welling was glazed and reddened and there was considerable tu diencess and pals. The ppearance of the swelling apert from the reddent pulsation gave the impression of an abacess about t burst Pressure on the artery above stopped the pulsati in the tumor. The swelling was diagnosed as an ancurism and it was decided to excise t.

The artery was ligated above and below and the save which contained conneterable amount of blood-dot was excused. The aneurism was a curious mixture of the fundorm and sacular an upper part the artery seemed to have a radually dilated into a fusiform channel and then suddenly a sac was formed in its course doubtless from the more complete rupture o stretching of the coats of the vessel.

The patient made an uninterrupted recovery the wound bearing by first inte ti n. It may be men tioned that the patient s arteries were atheromatous and he had a double sortic murmur

nurmur Ezward I., Cornell.

Neuhof S. Diagnosis, Symptomatology and Therapy of Dilatation Ansurisms of the Descending Thoracic Aorts. Am. J. M. Sc.,

The author recognizes dilatation ancurisms of the descending thoracle norta as a distinct clinical entity presenting characteristic symptoms, and reports a number of illustrative cases.

06, ch. 7 5

The most constant sign is an impact area to the left of the seremum at its middle third. By placing the eye on a level with the chest a distinct heav ing area, distinguishable from that of the space and occupying the lower left sternal intercostal spaces, can often be detected. A sense of impact is also recervised to the left of the sense of the sense will detected by mudy futting two or three fingers in the left middle intempaces near the sternum (Constantily a switcile third its pairpalls. In some instances it is possible to detect a difference between the time of the apex impact and that in the left middle interspaces near the stemum. This is best done by placing one finger over the apex and another over the left sternal border. These signs are made more evident by having the patient hold his breath.

There is usually a rough systolic murmur over the dilated aortal area the second sound has a liquid rather than an accentuated tone and is prolonged so as to occupy the entire diasole or is followed by a diastolic murmur of varying intensity Pain when present is substernal, or may be referred to different parts of the chest, neck jaws, or head, and is most apt to occur after exercise. These signs are usually associated with some evidence of cardiac decompensation which may not however be a marked clinical feature.

The impact to the left of the sternum and the characteristic murmurs suggest the condution, but it is absolutely essential to have roentgenograms or a flouroscopic examination to clinch the diagnosis. To condition is a leutic manifestation and in all cases antisyphilitic medication is indicated

J W TURNER

Bernheim B M Choice of Operation in the Cure of Aneurisms of the Extremity I tert M J

As so many surgeons are poorly prepared to suc cessfully cope with aneurisms, Bernhelm offers several suggestions to assist in making a proper choice of procedure in aneurisms of the extremity

The test devised by Moskowicz is recommended. This comusits of rendering the leg bloodless by an elastic bandage applied to the upper pole of the aneursm the blood stream is then shut off in the parent vessel by a pad in Hunter's canal. When aneursm is stilled the elastic bandag is quickly removed and the returning hyperemic wave care fully noted. Should the blush quickly spread throughout the leg compensation circulation is assured and the parent artery may be occluded Should the leg remain pallid collateral circulation is absent or slight and or lusion contra indicated.

Again normal pulsation of the arteries of the foot show an absence of compensatory circulation while a lack of pulse practically assures sufficient collateral blood supply

A case in point is given in which an aneurism of known syphiliti origin and of rapid growth was found in the popliteal space. There was pulsation of the arteries in the foot and the Moskowicz test negative. Therefore after removal of the aneurismic sac the gap was bridged by a venous transplant from the saphenous ven care being taken to reverse the ven so that the valves faced the foot Immediate recumption of the blood stream occurred the arteries of the foot pulsated normally, and the troublerome symptoms of ordems and numbness en turled disappeared within a short time

P M CHASE

Makins, G: The Importance of Auscultation in the Diagnosis of the Vascular Injuries Accompanying Gunshot Wounds La d Lo 1 19 6 exc 8

The author reports his experi ace in dealing with injuries of the blood vessels during the war

He lays stress on the fact that in any case of swelling of the limbs in connection with gundout wounds the stethescope affords a rendy means of establishing a diagnosis if there is an aneurism present. The point at which the brut is loudest and highest pitched will show where the lesion is situated. Aneurisms involving either the arteries, or the arteries and veins show in allition to the local bruit at their site also a transmitted brut in the region of the heart.

The author has not met with any instances in which a pure arterial murmur in onnection with the wounded vessels of the arm was audible in the heart but he has noticed it in a carotid aneurism and has frequently seen it in onnection with the femoral vessels. These transmitted bruits show a temporary persistence. The heart at inveit is mark edly affected enlarged and with an in reased rate after a few weeks it is able to compensate at which time the bruit disappears unless closely associated with the heart. He think that the art liac disturbance is probably to be explained by the sudden afteration in the force required for the maintenance of general circulation under the altered conditions.

Elsberg C. A The Surgical Significance and Operative Treatment of Enlarged and Varicose Veins of the Spinal Cord 4 m J M Sc 19 6 ch 64

Among vascular learns of the spinal cord such as amnesia, angioma et allargement or fortuosity of the superficult vens although relatively common have received little attention in the literature. When the posterior spinal vens are compressed by an extramedullary neoplasm the vins for some distance below (on or both of the two main trunks) appear engorged and sometimes more tortuous than normal. The appearance on exposure of the cord is quite different from the pinkish hyperamic look of the distended arteries indiving a minimal matory processes.

The operator should recognize the significance of these enlarged and tortuous veins. A local enlarge ment or varicosity may take place causing local spinal symptoms rellevable by operation. Cases have been reported of varices or hemorrhoids of the spinal pia the symptoms of which are usually those of a transverse lealon.

In several of the author s it cases the calarged vem accompanied one of the spinal roots to the dural opening. The abnormalities were of various kinds the calarged ems usually pressing upon spinal roots. These were in the dorsal region as five lumbesacral in one. The cond toon was always unlateral proving it not to be due to the operation.

itself. In one case a suberculoma of the cord was present. One case examined microscopically showed hysline degeneration f the vessel walls. The author's technique in operative treatment consists in the removal of as large a part as possible of the enlarged well by ruising and ligating w in fine silk in an aneurism needle. As the veins are very fragile prest care is necessary.

The results were improvement or relief in all but two cases which had splastic paraplegis 1 ng standing. The auth r is uncertain as to whether the venous condition is a cause o effect of spinalcord disease and thinks the operative result may be due to the decompression by lamineet my

POISORS

HORACE BINNEY

Tullidge E. K. Tetanus; Surgical Complication in th Present War Y 1 M J 9 6 cm oz

Tetams is a very common complication in the present war. There is usually a mixed infect present. The anarrobic nature of the organism is especially suited to the ragged and deep character of the majority of the wounds. The filthy condition of the soldiers, especially their contamination with ground which has been fertilized f ages, prechaposes them to inoculation with the tetanus bacillus whenever a wound is installed.

The usually prodromal symptoms are stiffness and pain in the muscles, especially those of the head and neck. These steadily increase in severity until

convulsions ensue.

The use of antitozin is highly recommended as a cursifive measure. Enorm an does are used by the autho. From 10,000 to 60 000 units being given. The local treatment of the w und is important and the liberal use of tincture of iodice seems to be beneficial.

1. E. Struss.

beneficial. J. H. Semen.

MacConkey A. T., and Zilva, S. S. Iodine in

Tetanus. Brit M J o 6 1, 41

It is a well-established fact that lodine when mixed with teams torin possesses the power of rendering the latter non-toxic. The longer the period of contact between the oldine and the toxin bed re injection the less tod the latter becomes A mixture of equal parts of lodine and tetams toxin also possesses the power to produce immunity

to subsequent inject in of the torin.

These facts suggrested the thought that iodine might be of value in curing tetanus, and series feeperiments was carried out with that in view. The conclusions reached are that solune when injected subcutaneously has no effect upon tetanus torin which has also been injected subcutaneously indifferent place. The course of tetanus can not be favorably influenced by injections of lockne alone nor does the latter seem it have any effect in enhancing the power of antitetants serum. Iodine can only be of use when applied it in infected focus, so that it comes into direct centact with the toria before absorption.

E. K. Austrasoo,

Robertson H E. The Prophylactic Use of Tetanus Antitoxin. 4 m J M Sc 9 6 cli, 668.

Robertson in reviewing the prophylactic use of teanus anti: tina, explaits its failure in some cases by pointing out the rapid formation and bacrption of tetanus come, associated with the extreme rapidity with which it is bound to the nerve-cells, when t cann t be neutralized. The bacrption of the antitotin it to the blood is relatively slow allowing tim f the more rapidly formed textin to gain such headway as to produce f tail results.

An ther reasoo for the fallure in some cases is the short duration of immunity conferred by the prophylacti dose, usually fifteen to wenty days. When for one reaso or another the formation of the total is delayed or not absorbed (delayed tetanus) the period of protection has passed and the disease develops. I tive unificial interference in wounds of patient that have remail ed free from the symptoms for may days or weeks act we symptoms of the us will suddenly fold we reopening of the wound an imput tion. Consequently when the interference is contemplated, a second like:

tion of ant t in should be dministered.

Other of his to clussons are that the most ideal and perfect protect against tetanus is the protect!

of ctive immunity prod ced before infect on has occurred. This admittedly is not

practical, b t deserves further consideration and research

In a large majority of cases the subcutaneous injection of twenty nits immediately after the in jury will prevent with certainty the occurrence of tetanus. The delay I a few bours in making the injection may mean the loss of life.

Local polications of fluid antitori n wounds are efficacious but unnecessarily wasteful nd not always practical

In cases where injections cannot readily be made, especially in war tim the immediate application to the wound i dried automation tampons in steened by clean fluid may be used as a temporary substitut until fluid a t t u can be injected.

D L DESTAND

Everidge, J. Mental Symptome Complicating Case of Acute Tetanus During Tre tment by Carbolic Injections. Bril M. J. 9, 6, 1, 443

Eleven days after havi g received severe in-Jury t the lower extremities, the patient developed tetanus, which rapidly grew worse. Antitetanic serum was given together with cem of carbolic acid sol tion subcutaneously every four a week the spasms were so severe that the patient was given large doses of morphine chloral, and bromides. At the end of this tim the spasms became less marked but the mental condition showed a great change a condition resembling delirium tremens developing. This lasted five days, during which time restraint was necessary Incontinence of urine and faces was present also Chloral and bromides had no effect but neraldehy de had a quieting effect. A relapse occurred with more incontinence and it was a month after the development of the tetanus before the patient's mental state once more approximated the normal

The author wonders what the connection is between the carboli acid injections and the condition. One c m of th 1 o solution was given every four hours over a period of about 12 days.

E. K. ARMSTROYO

Dean H R and Mouat T B Bacteria of Gan grenous Wounds. J R i m W C p 916 April 349

The authors grean interesting a fount of a prolonged study of the bart in a in gangrenous wounds at the Third Northern General Hospital which has brought out points of great interest to the bacteriol ogists and surgeons as shown in the following sum

- t The series comprises 18 axes of gangrenous wounds of will by only were fatal. Included in this total are 4 axes of teature, 1 of which was fatal and 4 cases of gas gangrene 2 of which were fatal. Among the 18 case bacillus adematis maligni was found in 3 and ba illus aerogenes capsulatus in 13.
- 2 Barillus perogenes capsulatus and bacillus orentul maligum are apparently possessed of pow erful enzymes. The tormer is peculiarly able to attack carbohydrates the latter proteins. Doriet's egg medium is an admirable medium for both microorganisms.
- 3 The shape size staining reactions and capacity for spore formation of these bacilli are profoundly influenced by the nature of the culture medium
- 4. On Donset's egg medium the majority of the barillia are typi alin happ uniform in aue and are gram positive. On media which contain a carbohy drate from which the bacilli an form acid growth is at first rapid and vigorous but after a few days the barilli become atypical in appearance vary greatly in air and the majority are grain negative.
- s Ba ullus aer genes capsulatus forms spores on Dorset s egg medium and inspisanced serum but not on media in whi h an aud reaction is produced Bacillus refematis maligni forms spores less readily in acid media.
- 6 The presence of bacillus aerogenes capsulatus and ba'illus redematis maligni is not necessarily associated with the development of gas in the tissue.
- 7. Brellus edematis malgin and ba illus aerogenes capsulatus re ese mitally approphives. They have little or no power to multiply in hiving tissue. In dead tissue they grow rap dly and produce poisonous substances by which the adjacent living tissue is destroyed and rendered a suitable medium for the further multiplication of these bacilli.
- 5 The bacilius tetani was not tound in ulms made from the discharge in any one of the ix cases in this series in which it was present
 - o The recognition of bacillus tetani by pu ely

microscopical methods is compliated by the fact that slender gram positive rods bearing an at solute is terminal spore may be occasi naily found in purcultures of bacillus edematis maligni and bacillus aerogenes capsulatus. Moreover pure ultures of tecanus bacilli especially viltures on egg medium often contain many aivri all firms.

to If broth is inoculated with material tron the wound in a case of tetanus and in ulated under anaerabic conditions the presence i build tetanic can often be satisfactorily dimensional annual inoculation. Such a broth culture should be a mined at intervals and two or three eeks may elapse before build it etanic can be fem nstrated.

The presence of hailful teram was demonstrated in the discharge from the sun is of two patients who did not be diplication of teranus. Both had received injection if antitetanul serum

The discovery of baillus tetani in the ounds of a pattent who had in it devel pel tetanus voild obviously be an influential from or more prophylactic injections of antitetam serum But the practical utility of such a procedure is limited by the difficulty and delay with hattin 1th 1a teri logical recognition of this barillu. No baillus tetani belongs to the same group fan in 1s. betria as bacillus acrogenese capaulatus and 1s allus elemanis maligni. All three have probally a min in urce and the conditions favorable to their growth within a wound are probably idential. The leministration of either bacillus cedemais maligni or bacillus aerogenese capaulatus is a rel tit. It implimatter and does not involve much lelay. The lic very of either of these bacilli might, it hadvantage be followed by a prophyla tit inject on it antitetanic serum.

13 A prophylactic injecti n of antitefani serum should be gi en bef re any c n Her ble operation is performed on a pati nt ith a kangr nous wound I. A I C RDE

SURGICAL ANATOMY

Horrax, G Studies on the Pineal Gland. Arch Int.

Attention is directed to the fact that the clinical aspects of pineal t more have been abundantly dismused alnce one when Frankl-Hochwart suggested the possibility of a pathognomonic syndrome. Marburg especially has developed the subject emphasizing the associatio of adiposity which he regards as an indication of overfunctioning of the gland. The salient factors have been gleaned from reports of about 70 cases of tumors of the gland Of this number only a occurred before the are of puberty and these, therefore, represent the source of evidence of that special train of symptoms, which have come to be associated with nineal disorders. namely premature development in the realm of both primary and secondary sexual characters. In several of these cases moreover principally in th earlier reported ones, the case records are in sufficient or wanting and in fi e others no reference is made to the sex organs, although certain met bolic symptoms are noted. Of these, diposity drowsi ness, and polyuriz are the most frequent suggesti g at once an implication f the pitultary b t the m perfect records preci de any possibility of settlier this question at present. Remarding the other cases. of which there are bo t to all but on occurred in young boys between the ges of nd The exception is Marburg a case, a girl o years old

The author reports three cases from the surpocal service (the Peter Bent Bentham Hospita, all f which showed precocous dolescence and er growth. A study of the disease to which the phecal body is subject has been confined almost exclusively to the different varactes of cumors which have been found to arise either from the gland fixelf or from those tructures which lie in a timmediate neighbor hood and therefore involve the placed secondarily very rarely co diffices other than tumor have been mentioned in connectil a with pincel pathology but these plays an inconspicuous. I perhaps d bit as

part I this chapter of the study of the sland. From the uthor study he gathered the impression that from what is known of the physiology of the normal gland, as well as from the results f I'on and his will experimental observations, that sexual ripening occurs when the pineal ceases to be fun tionally ctive or when it is removed and o this bash he inclines to the belief that the tumor in most of these clinical cases is associated with an inhibition of the normal products if panenl secretain If this were really the case, however one would suppose that gla dula feedi g would postpone adolescence, but from the observations of D na and McC rd the reverse seems to occur. The author's wn studies in this direction with the feeding of young guines pigs and rats were not conclusive and it is a matter which deserves further study Briefly the author gives the follo ing summary of his work.

1 Extirpation of the pineal in young chickens and lower animals tends to hasten normal maturity T more if the pineal gland in children, occur

ring before the age of puberty usually give rise to a syndrome characterized by precocious delecence. 5 Feeding th gla d substance to young animals is said to have the same effect as entirpation, but

the observations are somewhat inconclusive.

A report of three cases of supposed pineal tumor one of which was confirmed by personal is offered as

one of which was confirmed by necropsy is offered as a further contrib tion to the study of this gland. GEORGE E. BELLEY

Vecchi, A. Critical Observations and Experimental Researches on the Regeneration and Neoformation, f. Lymph-Glands (Oservation) of the nectric permental in rignerations is coformalone delle infoghiandel.) Clis. dev. Milano, 9, N. 90.

The uthors experiments were carried out on dogs and rabbits. The basis for the subsequent conclusions were dependent upon the following problems: Could totally enucleated lymph gland regenerate. Could partially resected lymph-gland regenerate. Could there exist independent in y damaging operation, a reoformation of lymph-glands, and could their n mber be increased in given region? The conclusions are as follows:

t After the enucleation of a lymph-gland there is no regenerate but the formation of a new lymph cland of substitution

3 After the partial resection of a lymph-gland cure is obtained with the formation f electricial tissue without regeneration of the part excised.

3. In particularly in that continue it is possible to obtain coformatio flymph glands, which increase the number flymph glands of a given region, either by proliferation of the pre-cristing gland, or by the transformation of the adjusce tissue (according t Bayer) or by the development of embryonal ecems.

Hoskins, R. G. The Present Status of th. Adrenal Problem. J Lab & Cl. Med. 9 6 1, 5 2.

The thor reviews the literature during the past ten years of summanues the work that has been done in this is been II comes to the conclusion that the fundame tal question remains yet to be answered, Why does the removal of the adrenal glands cause death? If believes that the trend of the evidence on wealable taggests that measular metabolism is at fault. If that be true the solution like that of an x-another of the most pursuing medical problems, rests in the hands of the bological chemists.

Stewart G N., Rogoff, J M., and Gibson F S. Th Liberation of Episephrin from th Adrenal Glands by Stimulation of the Splanchule Nerves and by Massage, Studied by Monas of the Deners ted Eyo Reaction J. Phermatel. & Exp. Theory 6 & ill, 205.

The observations of a n mber of investigators have indicated that during electrical stimulation of the splanchme nerves epinephrin passes into the curvaliation by the addrenal vans. These observations may be divided into two groups. (1) those in which blood has been collected from the adrenal veins of one animal and tested for epinephrin by its action on the blood pressure when injected into the veins of another animal (2) observations in which the liberation of epinephrin has been deduced from changes in the blood-pressure or other reactions in one and the same animal.

It is shown in the present study (on cats and dogs) that the response of the denervated eye to stimulation of the peripheral end of the splanchine nerves is due solely to the passage of a substance in the lood stream from the adrenals to the eyeball.

I When the venous path is blocked the response fails but appears on releasing the block and at the same interval of time as when the vessels are free The active substance must therefore have accumulated during the period of stimulation of the nerves behind the block

2 When the heart is stopped by stimulation of the peripheral end of the vagus atimulation of the splanchnics produces no effect on the eye. But on allowing the heart to best again the eye response occurs t approximately the same time from the moment of re-establishment of the circulation as the time interval between stimulation of the splanchnics and the response with the circulation is going a normally Duning the stoppage of the circulation of the splanchnics must have caused liberation of the aplanchnics must have caused liberation of the active substance at the same print from which it starts when the splanchnics are stimulated without cardiac inhibition.

When the circulation is slowed without being st ppel as by producing parilal inhibition of the he rt th ugh the vagus or by hemorrhage the interval between the beginning of atimulation of the structure and the appearance of the eye response

is c rrespendingly increased

1 It possible to find a strength and duration it ulation if the aplanchnics with which no ever proceed to be ablanced when the lipilateral or both could are clamped it ut which vill give a regime with the action free with longer or an erest mulation response for a belated one multiple of the strength of the carotide stamped. The lipilateral is the response and fits retardation can be until the strength of the carotide stamped. The first the free pages and the results of the strength of the

who deenaling is injected into the left renal not the central and of the femoral vein, in the central and of the femoral vein, in the central and in the produced by a given in the produced by a given in the produced by a given in the temporal follows is sensibly the same of the produced by the produce

eye while the clamp is still nor only after its rimoval or both during the application and after removal of the clamp. There is some variability in this regard in different experiments. There is also a somewhat greater varial lity in the time interval at which the response pipear, than in berval tions in which the splanding variational difficulties free or with the inschanged. The interpretation of these lift renders it do used.

Circulation time measurements she that there is always more than sum tent time for a substance to have been carried in the blood from the adrenals to the eye before the appearant the

eye reactions

8 The latent period filbera for a epinephrin from the adrenals in stimulation fith splan him is short since the tim interval after high the eye response occurs is sensitly the same is evoked by splanching timulation in the level fith adrenal it a quantity of adrenalin sufficient to elicit a responsion similar in character and amount

o The manmum period it immulation in the splanchines needed to liber to sufficient epinephrin to elicit a response in the finite sted eil ers brief (a fraction of a coold). With a surrent of given intensity the am until ithe response increases up to a certain point with the furation in this stimulation.

To Massage it no rit thadrerals cause den nite eve response in an inmal ir in histimulation of the planchnics his been causing it and at the same interval fitting. When after repeated excitations of a splanchnic nerie the reaction of the eve ceases to be obtained it an tilling general be clicited by massage if the corresponding drenal. But this reaction is soon exhauted.

rr Good eye rea tions have been bitained by stimulation of the splan hincs in cats in which attempts were made bef re the experiment to exhaust the epinephrin store of the adrenais for example by Inghtening r by administration of morphine. It did n t cent that it was easier to exhaust the capacity f the splanchinc nerves for eliciting these reacti as in u h animals than in animals which were guarred as much as possible against preliminary exhaustion of the epinephrin store by psy hical fixturb nees

PADIOLOGY

Kuegla, F. H. Radio-Activity as a Therapeutic Agency Med Hersid, 9 6 v 72.

Aft r reviewing briefly the event which led to the discovery of the roentgen ray and such radioactive elements as uranium and radium the author describes their applicability as therapeutic agents. Regarding their relative values he states that they are practically identical in their action, differing only in the quality and quantity of the rays produced. The choice of one or the other depends upon the natomical location of the diseased tissue and the peculiar requirements of the case to be treated. He lays stress on the matter of proper dosage and tech inque if beneficial results are to be obtained.

Among the condutions mentioned in which indioactive treatment was found to be particularly useful, were enlarged lymphatic, tuberculous and lymphocytomatous glands dymmenorhora uterine hemor rhage and ibroids at or near the menopouse yielded uniformly good results. Chronic joint diseases and even some selected cases of tubercu lous joints showed a fair percentage of cures or improvement. In the latter cases the author believes that the simultaneous use of Biers hypernemia treatment enhances the effect of the irradiation. In exophthalmic gouter the results were so favorable that he believes with Sidmann and Schwartz that it is to be preferred to surgery where simple medical treatment has failed.

Regarding the use of radio-activity in cancer the author quotes a summary from an article by Russell to the effect that its use in no wise should supplant operation unless it be in the removal of certain uperficial growths but that it be used rather as an adjunct to surgery

ADDER HARTON,

Perkins C. Wr The Normal Stomach; Its Size Position, Form Tone Peristalsis and Mobility from a Radiographic Standpoint Med Press &C c 9 6 u 258

After an examination of 58 normal stomachs radiographed in the vertical position and filled with an opaque meal of buttermilk and bismuth subcarbonate, I erkins draws the following conclusions

- I Peristalisis does not seem to exert any influence on the tone of the stomach, for we may have exag gerated peristalisis with a hypotonic stomach and diminished peristalisis in a hypotonic stomach.
- 2 There are no determined fixed points of any type of stomach in the abdominal cavity except the cardiac portion \ stomach may be of any of the types and yet be normal from an \ ray standpoint
- The average normal stomach is orthotonic. The usual position of the orthotonic stomach is as follow greater curvature (lowest point) one to two inches above the interpanous line either median or to the left lesser curvature (lowest point) three to four unches above the same line median or one to wo inches to the right. The plorus 15 placed two or three inches above the line in the median posit in or one and a half unch to the right. The axis of the stomach is vertical and parallel to the median line. The length is eight to ten inches and the width three to three and a half unches.
- 4 The 1 indency of the male stomach is always toward hypertonicity while that of the female is

toward hypotonicity. The temach in real and as high in the abdominal corts as miny textices of anatomy teach. There is no tructure in the human body however that his unharrant in no form tone and position.

5 Radiograph cum num in the by the fluorescent screen or late i the shear in the od of ascertaining the aniDm digitin i me peristals is and mobility ii the time little fore bearing in mind that the little little little stomach should be or service the little li

Hernaman Johnson F Th Uses and Limitations of Stereoscopic Radiography in the Diagnosis of Injury to Bone the After Treatment of Fructures as Carried Out in the Electrical Department of the Cambridge Hospital Aldershot P L L 143

ell I I I I II ii r lio-The method ha graphic work. It an neith ribe I pen if with nor employed to the cluit i the all known procedures as for in ting in Ix living ther foreign bodies. It is sentil in the liagnosis f injuries to the should r spin peli ad hip In these regions plates 1 one plane may be mi leading and the solid the tirxlu. I by the stereoscopic view is the only mean thecking the ofttimes mislealing appearante seen i an ordinary plate. By reversing the plates in the tereoscope an appearance is produ ed if on were looking at the other side of the bones under vamination. A bone or joint 1 never explored radi graphically until four sets of ter or ms ha e been taken, anteroposterior postero anteri r right lat ral and left lateral By means of u h plates a general view of the relati ns of the various bones can be obtained yet one must remember that the exact relationship of distances will be distorted. It is usually possible to say whether a bullet i at one side or the other of the bone or buried within it and to determine the relative position of fragments but the stereoscope must not be regarded as an instrument of precision for localization purposes

The author inda that the use of electricity in the after treatment of fractures is a distinct advantage where massage and passive motion have not restored the member to normal use. He advise, a combination of galvanism with a mild faradism in the form of baths. With a continuous current of 10 to 30 milliampieres used for 20 minutes daily the faradic current must not be of sufficient strength to cause any distinct muscular contraction. Massage and muscular exercises must be used in conjunction with the electrical treatment if the best results are to be obtained. Fractur's in the neighborhood of the elbox wirst and lankle will giv a n rmal result.

under this method within a month to six weeks. Where weakness is complained of in the limb con sequent to fracture the uthor advocates rhythmical electrical stimulation by the faradic current preferably by a Lewis-Jones electrical apparatus arranged to give at least so impulses a second. Such condition of weakness may occur after prolonged immobilization in which all the muscles in th vicinity are affected, o where through fulty noution a particular muscle group has been over stretched. In the latter case, a relaxation splint is essential for cure. In general up t a certain point the paretic phenomena re no doubt largely physical, but there is from the first certain mental element present, a kind of failure of memory as to how the lost movements are to be provoked, in other words, a lack of action patterns in the memory of the movement of the affected part. Stim. f the individual muscles electrically nlation therefore, has its greatest usefulness under such conditions. There is type of pain complained of following fractures, where the ppearan of th limb has become quite normal again and the move ments good. The patients describe it as being like toothache. It is made worse by exercise and often keeps the patient awake at night. The application of the high-frequency current by the va u tim electrode, at first on the skin and later t sparking distance, gives relief in a f w days. In case pain is not relieved careful \ ray examina tion, with view to the possible detection of some definit cause as the presence of a small bacers cavity in the middle of the ew formed bon should be undertaken. \ rays are often of value in re heving pain and causing the disappearance of previous fibrous accumulation HARRY & SLOAN

Turner D. Report on th. Radium Treatment at th. Royal Infirmary Edinburgh, During th. Year 1915. Ed ab. M. J. 9. 6. 1, res.

Some interesting points have been presented in this detailed report of 64 cases treated during the past year 24 of which were mallenant and in operable of this class 8 being sarcomata in which better results are to be expected if they are fa for ably situated. H also found carcinomat of the vaging and cervix would usually yield if localized but recurrence after a variable length frime was the rule. However during the i terval the patient enjoyed relief from pain, gained in weight, and was in fair health. A preliminary curettage is fren of great service. Screening has been found nnecessary in these cases, except to protect the healthy tissues the dosage should be t least 3,000 milligram hours. In rodent ulcers the results are invariably good, and if they recur t is usually due to insufficient primary treatment. The cosmetic result leaves nothing to be deal ed. For this reason Turner has employed it in the treatment of papillomata, mevi, and recent cheloids. Nine cases of exophthalmic golter were treated two of them being males. While there was very littl change in the gland, in fact in one instance it became larger yet the treatment had some influence upon the general system, for the symptoms were controlled and the health was greatly improved. In these cases a 4-mm. silver screen was used, so mg, of a radium brombide being placed a cm. from the skin and left in place for twelve bours. Under these conditions so damage was observed to the over lying integument. This treatment was repeated in or smooth.

in or 3 months.

The author believes that while the field of utility for the use of radium is limited its value in certain well-defined directions has been firmly established.

N. S. New Order.

Beck, L. G. An Accurate Method of Localization of Foreign Bodies in the Chest and Their Removal. Interst. M. J. o. 6 xxiii. 10.

thor discusses the value of stereoscopic radiograms : locating foreign bodies particular tress being laid o the fallacy of attempting to d termine from a singl radiogram the exact loca tion of foreign bodies, as well as the fallacy of at tempting to form a correct view of the position firagments after fracture To Illustrate this point thor placed bullet on the center of the ster Two radiograms were taken without change ing the patient position but the \ ray tube was shifted to a differe t angle. On each picture th bullet ppeared t be different location. The cases cited by the author attest the value of the method. In one get nee would-be suicide shot herself with 42-caliber pistol. The bullet from a single rad ogram seemed to be i the axilla. The tereoscopic readings showed the bullet to be against th scapula. It was found there. Beck uses the method in intestinal work in studying diseases of the cessory sinuses, in estimating the depth of

empyema ca ties and i fractures

Millwee R. H. Five Hundred Gastro-i testinal Examinations by Roentgen Ray. Texts M. News 9 6 xxv 4 5

Milliwer reports upon 500 consecutive gastrointestinal examinations by the roenigen ray with a barnum sulphate meal suspended in artificial butter milk. The roenigen diagnoses in these 500 cases were as follows.

Duodenal ulcer	ī
Proces tony and stasis	143
Appendix involvement	04
Gastric ulcer	48
Gall bladder involvement	30
Gastric cancer	28
Miscellaneous	10
Negative findings	19

The uthor was able t foll w p 80 per cent of these cases with the following checking. Of the cases operated upon for d odenal ulcer a lesion was found in the d odenum in all but one case this case had gall-stone with adhesions. Of the cases treated for duodenal ulcer all responded to

treatment except in

Fifty per cent of the positive appendix cases were operated upon all of which showed involvement In the cases of gastric ulcer and gastric cancer all of the cases operated upon revealed either an ulcer or a cancer with the exception of one case in each group which showed gall bladder disease with lhesions L. H SKIXYER.

Mullally G T : A Case of Tetanus like Spasm Localized to the Wounded Limb La 1 Lo d 9 6 cvc 867

Mullally describes a case of shell wound o the lower end of the femur which necessitated amouta tion. The case was complicated by gas infection whi h necessitated extensive opening up of the thigh A few lays after the injury twitching in the stump began and grew progressively worse the spasm becoming so painful that chloroform had to be given to control the pain. The author thought that he wa dealing with an ascending neuritis in the tump and resected the anterocrural and scrati nerves without relief. The patient died on the t nth day at which time the facial expression was suggestive of risus sardonicus. A prophylactic of 1 500 unit of antitetanus serum had been given th lay t the injury. The author feels that the ase no one of tetanus although there were no gent al pasms F D DICKSON

Weinberg M: Gas Gangrene in the Present War 6 st w 11 J 00 hor 24

(a gangrene has been especially prevalent in the procent war. The bacteriology of gas gaugrene ha been ca efully worked out. The bacillus aerogen s capsulatus otherwise known as bacillus peringens is found in nearly all cases. Only in ex ptional cases however is it found alone other or, asms being usually associated. These other rganisms may be diplococci, streptococci bacillus ert u and bacillus sporogens. Another com b n ti n of organisms occurs in which the bacillus i ulignant cedema (vibrion septique) is the pre 1 mi iting organism. Other organisms are usually u tid with the vibrion septique which is a I to elv rare agent in gas gangrene being found n nlv 4 ut of 100 cases.

1 th toxic form, the bacillus redematis is found at I with the bacillus perfrigens and vibrion Till in the classic form of gas gangrene From th for going it i readily seen that most of the ь m m relat d to the production of gas gangrene

Saint C. F. M. The Principles of Treatment and Their Application to Wounds. Brd. II. J. 9 6 4, 36

The principles of treatment are () remove the c use () ombat the flects (3) assist th reactio (4) prevent complications or deal with them f they have risen

Removal of the cause depends upon t location as to the probable press or eo absence funder. A superbual metall c body should be rem ved When deeply placed it should the removed unless the probability finites and proper X ray equipment is t in the d to all the socialization. Under special circumst neces even sterile built in may need to be removed for example when from its position it gl es ruse t irrutation of erres ter feres with the movements I joint etc.

In combating the effects the general condution of the patient is extremely important. Our transfered on from pain, secured if necessary by morphine, are bool tely essential. Stimulant must be given with caution small doses frequently given being preferably to large doses. Transism is the child remedy sallto being usually used preferably by rectum or subcutaneously but occass nail intravenously.

The treatment of the local condition in of ea th cont of of hemorrhage either by pad and presure for-press re light re—time, or vessed uture. The importance of ascertaining that no tourniquet is left on—limb too long is emphasized. In assisting the reaction the course foll wed

In assisting the reaction the course foll wed depe ds po the condition f the ound when the case arrives. Since most cases are infected in antisept is first used ind the wound thoroughly cleansed. Aseptic wounds may be closed and primary unline secured.

The complications remerous, one of the most important being sepas Thi is combated in a merous ways many antueptic being used. Hypochiorous acid is the most popular t present Efficient drausage lymph lavage secured by hypertom solution and Bit hyperemia are all imports a hastening recovery. The general resistance should be supported by fresh air quiet and plenty of nourishing food

The following rules have been elaborated by the a thor fighthe treatment of head niunes.

1 The wound was dressed, the lotion used for the removal of the old dressing beling in so car bole. Mercury perchloride was contra-indicated because odine had i vanable been used lavishly often producing bilitering. If further lavestlys itom proved 1 be ecessary, the wound was packed with spirit gaux wrung out of in 3 000 mercury benefit.

An anxisthet w dministered

The head was washed in in so ca boli lou n, and the hai sha red if whil the carbolic was
dripped n, following the razor

4 Th brused edges of the wound were trimmed with mouse toothed forcers, kinfe and selssors, dithe wound dried and swabbed throughout und ding exposed brail with pure carbolic cid. I more extensive wounds the exces of carbolic was neutralized by methylated sparit otherwise t.

SURGICAL DIAGNOSIS

Sewall H The Clinical R lations of Gra ity Posture and Circulation 1 / 1/ N

The va cular is stem sa "will" riwh r in a stat of tone by which it pa tvi till reduced. The tone tv keps the flood from tag nating unle the influence of grittin in the capacity reservoir of the abdomen.

The result of the kull keeps the brain related full ablow is seen with a zero of the latter of the below no notice her hand the black of the below notices upport perhaps than in a set of the transfer of the results.

tion. The physiological integrity of the splanchnic vasom to system and of the musculature? I the abdominal wall form the chief only extraneous limitations to expansion of the great bdominal reservoi

The splanchine vasomotor mechanism is sufficient to compensate for the effect of gravity on th blood supply of the brain. Deficient vasomotor tone combined with a tonic condition of the abdominal will operations abd men must unthe erect posture lead to deficient circulation in the brain circulation and cerebral anemia, as well as objecting of the

ecneral circulation In the normal subject the fall of carotid blood pressure which tends to occur on the ging from the recumbent to the erect posture leads to stimulation of the planchnic vasomotor center t the sam tim the tensio of the muscles of the abd minal wall is pparently increased as is evid ced by the difficulty found in making a satisfactory palpatory examination of the bd men with the patient pright. I these ways the hydrost ti pressure tending to surcharge the splanchni rems is impensated, so that with the ven us o off w from the lines, acceler, ted by gravity and the rterul inflow kept high by elevat o of systemic arterial press re th nourishment of the brain may be expected to flour ish in the erect posture

In the debilitated individual w must expect witness the preponderance of gravity effects proporti nal t the weakening of the physiological powers which had held ti compensation. Now in the erect posture the blood actually assgnates to degree in the splanchal veins at the expense of a systemic carculatin and the blood pressure in

the bru hial artery f lls.

In the group of complaining more or less bealthy looking a men in wh m it is difficult to localize the pathological co ditio — no which the physician commonly characterizes as neutrathenic measures taken t support the abdominal circulation often seem to give better result than any other methers into there is evidence of enteroptosis.

The one physical sign which seems indicative of reneral, and especially of it tracranial physicat the circulatory deficiency is the found in the postural changes of the blood-pressures I the ormal person in the erect t least i the sitt of postures the blood pressures is higher than when recumbent When the blood-pressures, especially the maximate found higher in the recumbent than in the sitting postures of the property of the

The treatment of abdominal circulatory tasis consists in respiratory and resistance exercise each exert in followed by a period of rest in the recumbent posture. B this with alternating temperatures, to joined with manage have I worable effect. The ubject should lie down for an hour after each

meal nd during the latter half f this period bag of shot weighing ten to fiftee pounds should be placed to be men Exercises especially adapt ed to strengthening the bd mind muscles should be imployed, uch as th rowing machle T lieve morbid yringtoms in the quickest way in artificial smooth properties to be the bard o correct

hould be polied over the I wer bdomen.

Sewall oncludes that pla hni stash is notentully present and may be the starte g-point for vicious circles f derangem nt in every case of general functional cakpess. Launess of th belominal wall probably leads in the erect postule to the est blishm t f a negative pressure within the abdomen, which it is prim bject of treatment orrect Depletio of th tracranial blood current must foll insufficient ompensation of the hydrostatic pressu vol ed i th erect posture Virtual memus (the brain lading t plicity if disorders is the natural sequence. It is probable that excess f blood pressure n th recum bent as impared with the erect post relise trust worthy inductor of all achaic tast \ En rango

MEDICOLEGAL, HOSPITAL, MEDICAL EDUCATION

Malpractice; Expert Evidence as to Treatment;
Patient Duty t MI imize Dumage Med
Rec 0 6 1 608

The case of D hl x W gner 5 P o70, was that of mt gamst doctor for malpractice in which the plaint of ecceeded braining a red et gainst the tee dong physical. The f cts at ted breefly re as follows

The plant ff with man, statistical injuries it his foot one import side catter of one of the bores and other injuries and bruises. The defends tiphysical was do notimet with the plant fift employer to treat the plant fift nder what was called the bospital few in man faction followed the wound and the plaintiff was infraed in the hospital for ver as weeks. After I ving the hospital for called a sax weeks.

mber of times upon the def adant fo treat ment At these visits the defeating divided him tues the foot and do some light work, and told him that he would probably have good foot. The dislocated cuncil rm bone was pressed downward and forward to such an extent that the protru ling end of the bone carried the wight of the body causing pain. The specific allegation of the defendant negligence was that the defendant is registered as a specific allegation of the defendant and the properties of the defendant of the conlaided to perform a operation by cutting the foot open and forcing the dislocated bone back into place.

The jury returned verifiet if you of the plain tiff but the trial judge set aside the verifiet potentiered judgment was obtain remide m for the defendant. The case was populated by the plaintiff and in appeal the above if its were practically and pounds outed.

шаприна

The main point in usue was Was the defendant guilty of malpractice in not attempting to set the dislocated bones by manipulation, the time passing when this should have been done should the defen dant have performed an operation? A medical expert for the plaintiff expressed the opinion that if there was swelling and infection during the acute stage an effort should have been made thereafter to restore the functions of the foot the presence of the swelling and infection would prevent resetting or operation during the a rute stage. The sooner the swelling vas reduced the better. Medical experts for the defendant testified that it would have been foolbardy to attempt to reset the bones in any way until all danger of infection had passed and the wound healed completely that the cutting of the tissues prior to this time would have been has ardous that the bon would not have r mained in plant it set that an operation might have made the dormant infective germs active threatening the loss of the foot and possibly the life of the patient that the duty of the operating or attending surgion was first to l k to the hf f the nationt They testif I that the services of the defendant were in Leping with the proper tea hings of surgery

The reviewing c urt save in substance that wher the unimpeached testimony of doctors of equal skill and learning disagree on a given state of fat the ours annot hild to the theory of one to the lusion fithe others that it a number of witnesses reogniz the method of procedure as priper and approve of it the court could not hold the surgeon guilty of malpractic giving reasons as

That a surgeon is called upon to exercise only reas onable care learning and diligen in his profession and the uses a method recognized and approved by members of his profession of equal 1 mining in 1 standing he should not be hild hably tor mistak nor will the court deem a man guilty of mily rate where doctors disagree a to method for thin in even though a mor in herm method thin the adopted is suggested a the finite? It is the duty of the attending up out 1. I what it is in able within the limits of profession 1 kill tor 1 main and suffering

The question then arise Dilth Italitin the case at bar violat any luty t the plaintiff after the plaintiff but lett the heatile Ih ut holds that although the district vith the employer of the rintiff tritit it it in the plaintiff left the h sq tal hi lut t th pl intiff was a ontinuing in tinuing t the limit t reasonable professi lithi It lings win ils clear that an operation of the t necessary and viullir () It is the uttring so far endued by the plaintiff of the lang offered to how that in a wn Fl w t u h operation ould appoint it 50000 the ourt therefore directed a judg thrith pluntiff t S∞∞ Hwyrth lint t i not hlt hable for the pain and suffer at in ling perits in The reason was the the diel two is notice for the original injury being ally in youth for proper care and ir atment and be u it the time the plaintiff left the hospital handler surgion and was a clithit in per ten would relieve him. He was under all all luty to minimize his damages. It toll ed thrire that h could not recover to the ntinu I pain an I sut fering because to as his luty if hoth ught he had been maltrated to hat the oper tion performed and bring suit for the reasonable costs there for

LOWARD L. CORYELL.

Kellogg, J. H. A Simple Method of Shortening th Round Ligaments of the Uterus for th Cure of Retroversion. If d. Rec. 9 6 1 vvl. 7 9

The method which the author describes has been used by him formore than twenty seven years. He has employed it in more than 600 cases a domany other surgeons also has used to extensively

In this operation almost without cepti curettage is required when the uterus has been long retroverted as a pathological conduit of the endometrion is almost louncibly present

When the pelvic floor is greetly weak ned, result

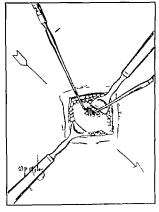

Fig Pkgupbgant

ing in rectocele or cystocele, these conditions must be corrected by a plastic operation,

Before or after the curettage the uterus is care fully replaced by bimanual manipulation care must be taken to see that both the uterus and the appendages are brought well forward released the uterus should remain in position. If it falls backward at once or settles down into a retroverted position adhesions are probably present

When marked anteflexion or retroflexion exists a stem pessary is introduced. A carefully fitted lever pessary is placed to support the fundus and to prevent all straining upon the ligaments pessames are usually retained for two or three months while the intestines are becoming readjusted and the abdominal walls strengthened

A separate incision is required for each ligament (Fig 1) and it is important that the incision should be mad at the right point. With the inger in the middle of Poupart's ligament the incision is started at a point about one centimeter nearer to the pubic spine and two centimeters internal to the ligament of Pounart

After the skin has been inclsed, the remaining dissection is made entirely with the blunt books The two points of the hooks are placed together in the center of the wound pressed into the tissues an I separated by drawing toward the angles of the wound By lifting the angles of the wound with the hooks the wound is made to gape an I the retractors are then introduced first one then the other this procedure i repeated a many times as may be necessary to reach the at neurosis of the When the aponeurosis first comes external oblique into sight it must be divided and drawn aside by the retractors in order to bring Poupart's ligament plainly into view

Fixing a point along the ligament about one third the distance from the pubic spine to the arterior superior spine of the ilium one contimeter internal to this point a puncture is made through the roof of the inguinal canal with the blunt hook held in the left hand and the tendinous fibers of the aponeurosis are split for about one half centimeter and the other hook introduced with the point turned outward toward I oupart a ligament The hook 15 dipped close beneath Poupart's ligament and what ever the hook engages is carefully pulled up (Fig. 2) If the ligament does not appear the hook is introduced again and made to explore the tissues one or two centimeters in each direction along Poupart's ligament If the ligament is not discovered the hook is turned inward and an effort made to and it beneath the outer border of the internal oblique where it is sometimes found

The round ligament may be recognized by the following factors (1) It is a distinct structure () It luffers in color from other structures looks white like a t ndon although not quite so smooth and glist ming as a tend n (3) Over the surface of the ligament mall tortuous e ns m y be seen which disappear wh in tracti - is made upon the ligament

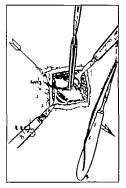

Fig. 3. Ligament folly drawn out and pertion cum stripped off.

and fill when the tension is related. It hould be teted that these wins are sometimes greatly enlarged and variouse. (a) The ligament is pulled out more easily than other struct res. When, however the herr which comes with the ligament is caught with it by the hook, the ligament is held back somewhat but by separating o cutting the nerve the ligame t may be very easily drawn up and does not map back int the canal as do other tlauser when released.

Failure t find the ligament may be d c to several causes

The ligament may be drawn down under the internal oblique to an unusual degree by long continuous and excessive strain

In very stout persons the ligament may be b ried in f t in the lower part of the canal.

3 The ligament is sometimes obscured by a mass of veins, due to a condition analogous to varicoccle in men.

4. more common cause of fallure is necessary placing of the locksion of the punct re through the roof of the inguinal canal. The ligament must be sought in exactly the right spot as bove described. If the hook is lattroduced even one centimete away from the proper point the ligament will be found nil with much difficulty.

The ligament should always be sought at the outer borde of the internal oblique and should be

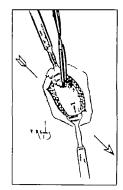

Fig. 4. Ligament d. nut above the external ring.

drawn out from d the muscl astead f being pulled p through it

5 The lig m in it is sometimes to slend that its ecognition is my difficult. Small ligaments remost likely the find in poorly diveloped women who have not borne hildren and in whom thours is retroverted than extremel legree.

6 Th ligament is sometimes so large that it is of readily ca git by th hook and ne is sometimes surprised after several min tes if finuless search by the sudd n ppearance of large strong ligament, fully half ce timet n n diamete.

7 The ligament is sometimes invested by fascia and f t and not so easily recognizable as i normal cases

8 Atomalous conditions of the ligament are sometimes though very rarely for d. In .603 cases the tho ha encout red conditions which may fairly be regarded as normalous in not more than half dozen instances

 Occasionally the ligaments re held back by adhesions the res it of pel-fc cellulatis involving the round ligame ts

The ligame t should not be seled with forceps. Treation is made while the ponch of princerum, which forms the canal of Nuck, not there tissues are separated and pushed back along the ligament with narrow-bladed forceps which are or released when the perit neum is fully stripped back but remain its hed as one pair after another is used.

As the perisoneum is stripped off the ligament may be pulled out more and more until finally so much resistance is felt that the uterus appears to be drawn up against the abdomind wall in the supra pubic region. The ligament will be seven to nine centimeters in length representing a shortening of fourteen to eighteen centimeters. No matter how slender the distal portion of the ligament may be the proximal portion at the point where it emerges from the canal will show a width of half a centimeter to three centimeters.

The ligament having been fully drawn out (Fig. 3) the next step is to attach it at its thickest part to the aponeurous of the external oblique at the upper angle of the puncture by means of a strong chromicized gut suture, passed from beneath the aponeurous A ligature is now applied to the shreds of peritoneum held by the forceps Thus closes the canal of Nuck and also ligates vessels.

which might be a source of trouble

If the ligament is anchored in this position by attaching the loop of surplus ligament to the anterior surface of the external oblique muscle the patient may possibly sooner or later develop hernia as the small intestine will gradually work its way out alongside the round ligament To obviate this danger the loop of ligament is drawn back into the canal and pulled up through the aponeurosis at a point five or six centimeters higher up and toward the median line. To accomplish this an aneurism needle is passed into the canal along the inner side of the ligament and made to emerge at a point five or six centimeters higher up and two or three entimeters toward the median line. About an inch of the loop of ligament is passed through the silk loop and the ligament is drawn back into the canal and up through the aponeurosis. By this means all danger of herma is eliminated (Fig. 4)

The end of the loop of ligament is again drawn under the aponeurous of the external oblique and made to emerge at the original opening through which it was first pulled out. Thus the surplus ligament is woven into the aponeurous of the external oblique to which it in a few days becomes firmly attached forming a very secure and permanent.

anchorage for the ligament (Fig 15)

The next step is to close the opening in the roof of the caus! Care is taken to pass the auture through the end of the loop of ligament so that when theopening in the aponeurous of the external oblique is closed the ligament is closely applied to the under ide. The roof of the ingunal canal is thus reinforced instead of being weak-need.

The superficial fascia is closed with No r plain catgut and the edges of the skin incision are approximated by two or three skin clips

The advantages claimed for this method of opera

tion over other methods are

t The abdomen is not opened hence there is no back and no risk of formation of peritoneal ad hesions and no abnormal conditions created which might lead to intestinal obstruction.

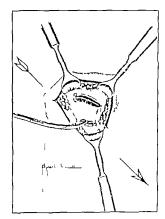

Fig. 5 End it ligament dra — 1 through riginal ope ing in roof i canal

- 2 The ligament is so secured that the recurrence of prolapse is almost impossible. In the original method of Alexander the ligament was cut off and attached to the faxor about the spine of the rubes. This method did not give secure anchorage and frequently resulted in complete failure because the ligament tore loose.
- 3 The ligament is not injured and no mutilation of any sort occurs so the patient cannot possibly be made worse as not infrequently occurs with several other methods
- 4 The technique is simple and the operation may be quickly done. The time required is rarely more than titteen minutes and often only ten or twelve minutes for both sides.

 5 The small and supericial incision and the
- short time occupied by the operation give no occasion for shock.

 6. The operation does not give use to complica-
- 6 The operation does not give rise to complications in pregnan as do some other methods
- 7 The results when the cases are properly se lected are better than those obtained from other methods

Conditions which contra indicate shortening of the round ligaments by this method are

I I rocidentia in which the ligaments are not stong nough to sustain the weight of the ntire abdominal to this ind a more radical procedure is constru

6 The corner and tight bands must be discarded definit ly and permanently

The nationt must live the simple life, and must make the care of the health a matter of serious and constant concern. It is especially important that she should understand that the operation alone may not effect a permanent cure, but that with her thorough co-operation it makes permanent cure possible.

ADNEXAL AND PERIUTERINE CONDITIONS

Rosenow E. C., and Davis, C. H. The Bacteriology and Experimental Production of Ovaritie.

J. Am. M. Am. 9 5 lvvi 75

The utbors record briefly the results of cultures made from the tissues and cystic fluid in a series f 64 ovaries removed at operation. The histories of a few illustrative cases and the results of animal experimentation made with some of the strains isolated are given.

Of 3 patients with acute tube-ovarian abscesses, a showed pure cultures of streptococcus viridans in countless numbers in the involved tissues. The ous of one of these was sterile while the other showed a moderate number I the same streptococcus. The third case yielded gonococci in large numbers. In 10 cases the cultures remained permanently sterile. In the remaining 51 cases, in which the ovaries showed the usual fibrocystic degeneration. streptococci were isolated in 29, the number f the colonies ranging from one or relatively few usually in the depths of the ascites-dextrose gar t hundreds, and in a few instances to countless numbers. They were present in pure culture 1 7 cases and associated in the others with the welch bacillus and a few stanhylococci or colon hacilli. Welch bacilli were found in small numbers in a cases diphtheroid like bacilli in to a few colonies of staphylococrus albus in o the gonococcus in a the colon bacillus in t and an eroble streptothrix i one.

The following facts support the view that the streptococci bolated from the chronic lesions when there was no history of a previous acute infection, as well as those causing acute infections of the ovary are carried to these structures by the blood more

often than is generally believed

The occurrence of fibrocystic degeneration of the ovaries in which the usual strentococcus was isolated in pure f rm in a young w man with im perforate visita.

s The history of tonsillitis followed by symptoms of pelvic infection in a number of patients in the series

3 The not uncommon occurrence of pelvic infection noted in gynecologic practice following anginal attacks during the menstrual period.

4 The far more frequent occurrence of so-called idionathic streptococcal peritonitis following angual ttacks, in the female than the male which, accord ing to Wilder who reviews the literature and reports a case in point is d e to the occurrence of primary hematogenous ovaritis and a secondary neritonitis.

c. The beence of colon bacilli in all but three ovaries in this series, a fact contrary to expectations if local invasion occurred commonly

6 The frequent concurrence of appendicitis. cholecystitis and arthritis in these patients, dis cases proved to be due usually to streptococci from a distant focus of infection.

The occurrence of fibrous and cystic degeneration in the overy secondary to scute injection is already well established. B t as pointed ut the cause of this condition without an acute injection had not proviously been worked out. In this work th authors have isolated streptococci, often in pure culture, and demonstrated them in the tissues in the areas sh wing infiltration roughly in proportion to the amount of tissue reaction in a large proportion of the ovaries studied Two of the strains isolated showed a marked affinity for the ovary in two species of animals - rabbit and dog - producing hemo rhage and leucocytic infiltration (precursors of scierotic changes) in and surrounding the granfian f llicles and in the ovarian tissue stroma containing

interstitial cells in the fully developed corpus luteum in a pregnant rabbit. Hence, the conclusion seems warranted that fibrocystic degeneration of the overy even in the

absence of previous acute infection is due commonly t a low grade hematogenous infection by streptococci having elective affinity for these structures. Owing to the fact bowever that the number of bacteris found is relatively small and that the experimental lesions in the overy are not du t an overwhelming growth it is dea that while excision and resection of ovaries is indicated in some in stances, it should no longer be done without due regard for the enstence of chronic foct of infection which may serve not only as the place of entrance but also as the place for the bacteria to acquire the peculiar properties necessary to infect the ovary. There is little indication for the removal of this type of ovary, with the idea that it may play the rôle of a secondary focus of infection we the second case in the series indicates that thus at times is possible. The results suggest however that the early cradical tion of primary foci of infection in this type of patient might in some cases prevent the premature selection degeneration of the ovary.

McGlinn J A The End Result of Resection of the Ovaries for Microcystic Disease. 1m J Ob t N N Q 6 lxviii 435

From his own experience and that of other open tors the author concludes that there is nothing to be gained by resecting the ovary which has undergone small cy it degeneration. He believes that resection tends to make the condition worse and either removes the more diseased ovary or simply punctures the evisit which are near the surface. The associated pathology in the pelvis must also be cleaned up. Following the operation the patients are treated to relieve pelvic congestion and if possible to prevent its future development. Five brief histories are given to show the futility of resecting the ovaries.

C. H. Davis

Llewellyn T H and Block F B: Hydrops Tubre Profluens. J im M i 96 ltvl 18

The patient was a very stout woman aged 33 She had been married for fourteen years, but had one child some years previous and no miscarriages The menstrual periods were never regular other month the flow was profuse while in the inter vening month it was scanty The previous history presented nothing of importance except that she had had her left tube removed four years before She complained of throbbing pains in the sacral and right ovarian regions associated with a vaginal lischarge A short time before while stepping from the sidewalk to the street she felt a sharp tabbing pain in the right side and felt a sensation a though something burst Immediately after ward a brownish discharge issued from the vagina and has continued to do so ever since.

It operation the left overy was found to be tran formed into a folleular cyst about the size of a peach the right tube was enlarged and con tained fluid while the right overy seemed to be in good con hillon. The operation consisted of a supra aginal hysterectomy in examination of the pathologic specimen after the operation was all left cophorocystectomy. On examination of the pathologic specimen after the operation was empleted it was found that when gentle pressure was made on the tube there was a flow of clear that the pressure was made on the tube there was a flow of clear the pressure was made on the tube there was a flow of clear that the pressure was made on the tube there was a flow of clear that the pressure was made on the tube there was a flow of clear that the pressure was made on the tube there was a flow of clear that the pressure was made on the tube there was a flow of clear that the pressure was made on the tube there was a flow of clear that the pressure was made on the tube there was a flow of clear that the pressure was made on the tube there was a flow to the pressure was made to the tube there was a flow to the pressure was made to

W. A. BRENMAN

Young E B A Simple After Treatment for Perineal Wounds B & # M & J & S J & 9 6

The method at the Boston City Hospital has been used for nearly ten years and has been generally adopted for some time as the standard treatment. The aim is to maintain the greatest possible degree of cleanlines and dryness as under such conditions infection and irritation are least likely to occur.

After twenty four hours when the bleeding has ceased the gaute penneal pad is somitted and the gentals and fissure between the buttocks kept liberally covered with a drying and antiseptic powder. For this purpose various mixtures have been used the best being the compound site rate of zinc with born eaded. Results have been good with the stearate of zinc alone but rather better with the boric acid added as there is its tendency to decomposition of whatever discharge may come from the wound or elsewhere. The gre t als vintag of

the stearage of sinc is that it sheds water and keeps the parts dry In practice it has been found that mixtures of tearate of zinc and boric acid made by the physician are not so satisfactory as those pre-

pared by the pharmaceutical firms.

The powder is best applied with the patient lying on the side the upper buttock being raised and the powder thrown into every fold. It is not ufficient to dust lightly o use the powder blower. The parts must be thickly covered, especially between the buttocks, and kept so throughout the healing if the best results are to be obtained. Although the powder gradually becomes moist, it gives ex cellent protection to the skin, is mildly antiseptiand sheds water to an amazing degree. With reasonable care it is usually possible temaintal absol to dryness.

If, as occasionally happens, there is considerable tendency to moisture and maceration of the skin. the application f per cent aqueous solution of icthyol before dusting with the powder will be

found effective.

The national free from any dressing lies posmall pad which collects any discharge from the vaging or elsewhere and can be changed whenever necessary. The genitals are calcully washed after urination and defecution and as often as may otherwise seem necessary

The advant ges claimed for this method of treat ment are drypess of the parts and hence less tendency to irritation and infection. There is also no perineal dressing to increase perspiration, bsorb discharges, and form poultice.

EDWARD L. CORNELL.

MISCELLATEOUS

Barnes, F M J Psychiatry and Gynecology Surg Gynes. & Obst o 6 avil, 579.

The origin of the belief in the causal relationship of genital to mental disorder, review of the theories which have been dwanced in explanation of the character of such relationship and an analysis of the data which has been presented in support of such theories are considered. Absolutely co tra dictory views have been held at different periods and the full gam t has been ru from dvisement of complet cophorectomy in genitally normal females t no -operative treatment in females with demon strable genital disease. Of the various theories which have been proposed the toric dendocrinic are today receiving the greatest attention

The facts vailable do not warrant the assumption that diseases of the overy or disorders of its internal secretion re in themselves responsible for the production of any psychoals. Statistics do not bear out the contention that gynecologic disease deserves the importance credited to it by some. The vast majority of mental cures reported have occurred in psychoses which were more or less acute and self limited Where operativ indications exist, and it is now the consensus of opinion that these are the same i the insone as the sane, the results obtained by operatio have been considered apart from the possible effect of such measures as are instit ted during the period of post-operative care

Although the menutrual period is accompanied normally by a crt in group of phenomena referable in part t alterations of function f th pervous system and although these are sometimes exaggerat ed in so-called nervous women, it has t been show that menatruat on itself is the cause of a neychosis. The calm judgment of the majority both psychiatrist and gynecologists, tends at present stro gly t the belief that cause of insanity t t be found in fernal genital disease or dysfun tion and that gynecological treatme t even where di ted by the gynecological aduti a. cannot be recommended as cure for psychoses

T ley H E. Hydatidiform Mole. Le mille M ath g 6 todi <u>130</u>

PREGNANCY AND ITS COMPLICATIONS

Montgomery E. E. Recognition and Treatment of Ectopic Gestation III II J 10 6 xx 54

The general practitioner should be so truined that the concurrence of sudden abdominal pain shock faintness feeble pulse and symptoms of profound animum will awaken the suspicion of internal harm orthage and this should govern his procedure in treatment.

The physician so trained will not ply such a patient with stimulants but rather administer a s-dative for he will remember that the vessel is open and that the only hope for relief outsile its direct control by -lamp or ligature is through the format in of a clot whose further action increased blood pressure vould imperil

As it cannot be assumed in any case that the clotting will be effective in the control of the hemor rhage the greatest certainty is through efficient closure f the bleeding vessel by its ligation and measures should be employed to secure this under the most favorable irreumstances.

Where it is not practicable to secure immediate surgical relief the patient should be placed under the influence of morphine and kept free from annovan euntil she can be placed in a proper environment fraugical measures.

Imm hately preceding or simultaneously with the in 150 of the abdomen active timulation the most efficient of which is the intravenous transtission of alline solution to which adrenalin has been added should be begin and continued during the operative procedure by which any a lditional shock through operation is more than counteracted.

E en though it is apparent that operation is not need d to ensure against further harmorrhage to pen the abdomen is advisable for the removal of the pattent are relieved though as the forces of the pattent are relieved from its care and disposal

Wilson, K. M. Nitrogen Metabolism During Pregnancy B II Jok II pt II p 9 5

The nitrogen met bolsmenthee normal prognancier was studied in on patent for period four weeks from the tenth to the fourceasth week I prignancy. The other two patents were studied for the last 3s and or days of their respective pregnancies of short time in the puerperal nervod.

Af urly liber 1 in was all ed Each article of food was weighed or meas red before bed griven to the patient and y resid silected od gain weighed measured. The pat int were kept under ormal conditions possible in regard to the conditions.

The urine was collected to its mity four hour periods and daily analyses made. From these daily analyses the daily a rarge introge content of the unif for periods of week it im was estimated. Daily estimate as of the amm als altrogen were made on all specimens and the mitoe-add offerene made on all specimens and the mitoe-add offerene was estimated for variable periods. The total network was estimated for variable periods. The total network was determined by the Kieldahl method the ammonia by the method of I olen, and the amm nitrogen by the Van Styke method. The faces were preserved and analyzed weekly and from the results obtained, the daily severage aftrogen content was calculated. The patient were weighed to frought the period of

All three patients were perfectly ormal with no nausea woming o other gastro-intestinal disturbance.

The onclusions drawn wer as follows

i In the perfectly ormal pregnant woman at rage of nitrogen begins at m ch earlier period tha has hithert been supposed possibly the organ ism may acquire the capacity for storing nitroge from the very beginning of the pregnancy

In the early months this storage is far in excess of the ctual needs of the developing ovum, and th excess must be dded to the general maternal rganism.

- 3 Storage of itrogen contin es throughout the entire d ration of pregnancy being most ma ked durf g the last few weeks, when the fortal needs re at a maximum
- 4. The nitrogen stored is greatly 1 excess of the actual needs of the developing ovum, so that apart from the mount needed for the hypertrophy and development 1 the genitalia and becaust, large proportion of the nitrogen stored is added to the general maternal grantsm as rest material, though concerning the form in which this reserve is stored it is impossible t make any positive statement. The nitrogen cavital of the maternal organ ment. The nitrogen cavital of the maternal organ.

ism is thus increased though the reserve supply may possibly be entirely exhausted during the puer penum and period of lactation

5 In the healthy woman who goes through a normal pregnancy the penod of gestation does not necessarily represent a sacrifice of the individual for the sake of the species but may actually be a penod of gain

6 There is a relative increase in the percentage of urmary nitrogen excreted in the form of tree amino-acids though not necessarily an absolute

increase in this form of nitrogen

7 There is also a tendency for the percentage of ammonia nitrogen to become increased during the last weeks of pregnancy although at other times during the pregnancy there is practically no variation from the percentages noted in non-pregnant individuals upon a similar diet. D. H. B. yo.

Kohlmann W Fibroids Complicating Pregnancy S th M J 9 6 445

In onsidering the treatment of abroids complicating pregnancy Kohlmann classifies the cases as follow

- r. The first class includes probably the majority of cases with h are without any clinical significance and do not interfere with either pregnancy or labor. The tumor may be discovered accidentally during an examination or post partium bleeding may lead to its discovery.
- 2 The second class includes cases in which the introd causes pronounced as mptoms which may prove langerous to the mother and feetus. In these cases enucleation of the tumors is advised.
- 3 The third class includes cases in which the location or size of the tumor or the associated displa ment of the uterus make an expectant treat in it extremely dangerous to mother and child in 1 in some cases a divery through the natural channel 1 impossible. In such cases pregnancy should be allowed to go to term but at the end of pregnancy or the beginning of labor ra heal treat ment should be instituted. The operation of choic should be exarted section with supray ag nal (1 orrea) or total hysterectiomy.

4 The fourth class includes cases in which the progress of pregnancy would increase the suffering and even endanger the life of the pati nt while abortion would be very difficult and dangerous on a count of the distorted uterine channel. Even after successful termination of one pregnancy there is danger of ucceeding ones. In succeases the uthor advises tot I hysteromyometromy of the graval uteru or supravaginal as recommented by Landau.

Porritt N. The Treatment of Puerperal Sepsis by Uterin. Suction and Drainage B + V J

The union tube has all the advantage with non of the danger of the unine lou he. In at least two ask the author his seen thousens douch on virtual martis pracma and a rapidly fatal gineral intection, while in another case it set up an action presum bly them all personni

Three c ses re reported in which the uterine contents are removed. The following in truments

were u ed

A plass Budin cath ter to which the inl t end of a Higgs son nema syn ge was atta h 1 was passed into the uterus. To secure the syringe to the Budin cath ter the inlet valve as re-The tube of the syringe between the bulb mo⊸d and the ath ter was held firmly and the bulb squeezed so a t drive out the intained air through the nozzi On releasing the pres are on the bulb, the vilv behind the nozzle closed and pre ent d the return of the air. Thir was then a acuum in the yri g and on r leasing the res ure on the tube between the lulb and the Budin sucti n was e erted through the cath ter within the Noair wa lr w nto th ut ru although the suction drew into the orities of the theter thick grumous sempurule t masses whi h wire too large to pass through ni wl n th cath ter

was withdrawn, came with it Reintrod ction of the catheter and suction drew out more of these

thick nieces.

Uterine suction discloses the condition in the interior of the uteros. It is most instructive to watch the gradual alteration of the matter with drawn from a thick, offensive fluid, loaded with semisolid purulent masses, to a clear red liquid and from that t an inodensive mucus. Moreover it prevents the physician from being misled by the deceptive character of the discharge found pon the pad. The pad may be covered with discharge which may be ally an overfl w or may not comfrom the penthouse in the terus t all, for there may be odorless discharge on the pad and f ul fortid fluid in the terus. Efficient drainage of the uterus is the key to successful treatment of puerperal sepals.

Two of the three cases reported recovered. EDWARD L CORNTILL

Mitchell, A. G. The Duration of th. Number Period in Women of th United States. Am. M 411 0 6, htri, 500.

An analysis is presented of almost 3 000 cases taken from the records of the Children's Hospital Philadelphia, during the last tifteen years As t was the desire t determine, as f r as possible, the ability of the mother t nurse ms y cases were excluded. It was the duration of the physiologic period of lactation, apart from disease or deliberate act of the mother which was the problem to be solved. Thus when the records showed that the mother stonged nursing from some such cause as going to work, or lactation was terminated by an acute infection or mammary abscess, the case was not included.

It may certainly be stated, boweve that the statistics to be presented show with reasonable accuracy the length of breast feeding i the bospital class of Philadelphia women These women are of different nationalities, including Italian, German. Russian, Armenian, Irish, and others. Many of them are notive born Americans and a fairly large percentage consist of Jewish and olored women

From the beginning of 900 to the end of 904 there were 134 cases in which the average length of la tation was 5.02 m nths. From the beginning of 1905 to the end of 909 there were 8.7 cases ith an average f 6.36 m nths. From the beginning of or t the end of 04 there were 58 cases with an average of 5 % months, therefore of a total of 8 9 cases during the fifteen years, the average I gth of lactation was 6 months

If it is borne in mind that this is a study of the statements of the poorer class of city women, the following conclusions may be justly drawn

There has been no decline in breast feeding in the bet gyear

The women of the poorer class compare f vor ably i the period of lactation with the women of the more prosperous class in this country

1 The women f this country compare favorably to the period of lactati n with European women. 1 The a rerace period of la tation in children entered at the honoital was 6 months.

Twenty ne cent of the worn did n t urse their childre to per cent med week or longer ss per cent ursed three months or longer 42 per ent ursed alx months o longer to per cent nursed nine months or longer a per cent nursed a year or longer a per cent nursed curities no this a longer and percent niedts years

6 Fo th reason that artificially fed bables re m re-susceptible t gastro-intestinal and nutritional disturbance the infant brought to the hospital were in the large majoraty of cases bottle fed at the tune of their ent ance there. The concluse it is inevit bl that the figures giv represent the minum mod la tatlo

h was a study of the statements of Sin mothers when questlo ed regardi g the length of tum their children were breast fed

EDWARD L. CORNELL.				

MISCRILLANEOUS

Gentill A. Histochemical Research Regarding the Function of the Decidum (Indexini atochimiche rignardant la funzione della decidua) d estet giere 9 6 evertil, 8

As the results of his researches on human and animal decidua Gentili finds that the decidual cells possess an essential function the laboration of lipoid substances belonging t the group of phorphates

The lipoidean function is in clear and precise correlation with the ellular vitality. If these elements are defective either there is lack of lipoid production or it passes into true fatty degeneration. The disposition of lipoids mone the protoplasms and the presence of granules of this substance in the inter-ellular spaces indicat the method elimination followed by the lipoids.

Ireata D : Analgesics in Parturition Clinical and Experimental Contribution (Los analcesicos en el part contribucion clinica y vpenmental) Rev Loc med Argent o 6 xm 93

The author has carried out extensive clinical in vestigations on parturent women supplemented by animal experiments in an endeavor to 1 termine the action of morphia pantopon hydrate of chloral etc on the physiological progress of parturition

Hysterographic methods were formerly employed but the older apparatus in which the ut time move ments were transmitted from within the uterus have been discarded in favor of external by terography the movements being transmitted from the abdominal wall in the region of the uterine fun lus and beyond the influence of respiratory a tion The transmitted movements are registered on a revolving drum

The results as summed up by the author are as follows

- 1 The toxic dose of morphine for guinea pigs may be taken as a coos or per gram weight of the animal 2 Hypophysary solutions do not dis intoxicate morphine
- 3 Maltose ferments not only do not dis into a cate morphine but appear to increase its toxic power in animals
- 4 The physiologic action of analgesics and partoanalgesics upon the arterial pressure and the uterus is equal to that of morphine
- 5 The union of large doses of morphine to small doses of hypophysary extract annuls the oxytoci
- 6 Solutions of mult ferments have an oxytocic action although more ephemeral than those of the hypophysis
- The general opinion that pain and efforts are factors which are opposed to morphine intorucation is without foundation. The properties of morphine injected during pregnancy may be transferred with out modificat on to the firetal circulation Sensibil ity to the toxic action of morphine is greater in the infant Personal susceptibility toward morphine varies greatly with the ubject. In 40 per cent of the cases there was not sufficient sedation of the labor pains to justify the use of large doses of mor-
- 9 I roducts with a morphine base distined to produc analgesia ar inconstant in their action and injecti n f such substances during the expulsion period have little effect moreover their administra tion in cases of ob tetrical intervention is not only uscles but prejudicial
- o Den att es of optum like all analgesies do not lessen the pains of labor but alter the uterine lynamic because they diminish the number and intensity of the ontractions. Compositions with a morphine base may intoxicate without lessening labor pains

to Cen rally the blatation and expul ion periods are prolonged in an lg siz I parturi nt duration of labor may be to hour in multipara-Artificial rugtur of and 24 hour in reinupir the membranes multill resorted to mir itriguintly in analesized womin lik is with obit in il inters niion

Walker J The Technique at the Jewish Maternity Hospital and Its Results. 1m J Dbu N 1 l u 1

The author outlines the general management of pati nts at the Jewish Maternit. Hospital and states that they have found the following rules necessary to good result

- All lelivenes shall be ondurted on the same basis as a surgical operation sterile draping of the patient and proper preparation proper cleansing of the operator's hands and the use of a teril gown and gloves
- 2 Making the smallest number of vaginal raminations limiting oneself to one or two and depending a good feal on external palpation for general information and the use of rectal examination for d timite inform to n
- 3 By allowing the pati nt to hav the proper test of labor and eliminating meddlesome obst tri-s
- 4 The careful watching of the feetal heart sounds and uterine ontra tion by n intelligent nurse thus saving hildren which otherwise would be stillborn
- 5 The more restricted use of pituitrin to cases in which full indications and
- All cases showing a temperature bove on 3 should be rega ded as suspir u and be isolated CHDVI until proved therwis

GENITO-URINARY SURGERY

ADRENAL KIDNEY AND URETER

Shannon, W. R. Experimental Gloudy Swelling of the Kidney in th Rabbit. J Lat & Cis. Med 0 6, 4, 54

Shannon defines Virchow's cloudy swelling (truebs Schwellung 1848) of the kidney and quotes the online of others reverding albuminous granules

and darkened tubulfi

Claiming that turbidity and aw li g of an organ re not always associated with increase f albuminous granules, yet on the other hand, there may be a marked increase of albuminous granules in the cells without the presence of turbidity or well ing an experimental study on rabbits was under taken.

In the first experiment compensators circulatory increase was produced by nilateral nephrec tomy or ureteral ligatio with removal of the other

kidney in forty-eight hours. In the second experiment ch mical irritants (tartrates) were injected subcutaneously and the kidneys were removed to t firty-eight hours theresiter

In the third experiment, autolyzed liver sol tio was injected intraperitoneally. In eighteen hours one kidney was removed the other was removed after the death of the animal.

I the fourth experiment infectio was produced by injecting cultures from pasteurella abacesses The kidneys were emoved from the rabbits during the different at ges of infection, thus getting the different degrees f the cloudy swelling

The ummary of the findings re as follows r The normal rebbit kidney at ye co tains, in the convoluted tubules course albumnous granules. Usually these granules are so numerous few tubules that they ppear dark in the in fresh tissue. The granules are pparently thin-walled vesicles filled with fluid. They re best fixed by solutions containing formalin. They are not fixed in solutions containing scettle cid

2 When e kidney is removed the dark tubules are increased in the opposit kidney during the first twenty-four or forty-eight hours, but the increase of albuminous granules is not sufficient to cause any definit change i the gross ppearance of the kidney

3 S beutaneous injections if tartrates produce swollen, cl udy kidney but there is no increase f albuminous granules The cloudiness and welling re apparently du t ordema, anzemia, tissue disintegration, etc.

4 Intraperitoneal injections of utolyzed liver tiasu produce a markedly cloudy and swollen kidney The albuminous granules disappear entirely. The gross changes re apparently due to the same factors concerned in the tartrat experiments.

c Chroni supputative p ocesses attended with marked emuciation cause an enormous increase of albuminous granules 1 the kidneys These stranules are often larger than the ormal and irregular in share but they seem to have the same chemical comnouti

6 Acut i temia cause rapid disappearance

f th normal albuminous granules.

ut toxemia superimposed upon a chronic supportative process causes disappearance

of th albuminous granules.

8 K dn vs which show n enormous increase of albuminous era ules usually eive pormal phtha lean output d the cells are usually intact form of cloudy welling is therefore probably not degenerative change b t a physiological remonse to an increase of protel waste product in the blood.

o. There is relat on between the f rmation of lbuminous granules and fatty metamorphosis. It is suggested that the term cloudy swelling

be discarded and that the several processes producg this poearance be considered separately C. E. BARRETT

Newman, D. Pyurla, Symptom: Its Ca ses and Diagnosis. Glasger M J 9 6 lrvv 6

Pyurl is symptom of many different lexions. Pus may manate from my pol t f the urinary tract from the kidney t the urethral meature. In every case of pyuris the important f cts to deter mine e the nature of the infection, the location of the lesi n, and the extent of harm which has resulted from the invasion.

To discover the presence of pas i the urine is important but to trace the cause and recognize the particular lexion producing the pyuria is necessary before any intelligent and flective treatment can be undertaken. Pyuria is nearly always d e to bacterial infection. I som cases the organisms are abundant and easily found and cultivated, in others, e.g. tuberculosis and g nococcic infection they may be hard to find and difficult or impossible All so-called sterile pyurias are into cultivat dicative of quiescent tuberculoris.

The reaction has been considered a rulde t the place fr m which th pus comes, cidity pointing to renal and alkalinity to vesical rigin. There is no foundation for this widespread belief. The reaction in these cases depends upon the organisms present. The organisms associated with acid pyuria are bacillus coli tuberci bacillus, streptococcus pyogenes pneumococcus bacillus typhosus and pyogenic cocci. The organisms which decompose urea and which therefore are found in alkaline unne are staphylococcus pyogenes aureus and albus gonococcus and bacillus proteus. In general it may be said that of all infections of the urnary tract in one third of the cases the reaction is sikaline and in two-thirds acid.

Following a brief discussion of the subject the author states that as a result of experimental in ours the following assertions may be made

I Simple retention of the urine does not give

rise to septic inflammation.

2 Small cultures of pyogen micro-organisms such as staphylococcus pyogenes aureus staphyloc cus pyogenes albus tubercle ba illus or bacillus coli communis when introduced into a healthy blad der fall to produce sepsis

3 If the mucous membrane of the Flatler be injured or diseased prior to the introduction of micro-ore nomes sensis immediately occurs

4 If the artificial retention of the urin 1 in duced from six to twenty hours after the introduction of a septi organism into the bladder suppura

tive inflammation of the muc us membran fillews.

The avenues of invasion are by the blood the lymphatics along the lumina f the extretory butts.

and by continuity and through wounds

The septic renal discuses are classified as follows in Purulent embell in ephintis a descending septiand suppur time lesion of the kidney without irresisting disease of the conducting and collecting portions of the urinary tract the septic virus being

conveyed to the kidney by the blood 2. Turulent interstitlal nephritis an ascending interstitial nephritis infection being by the lymph atics from a primary septi-fixed in the lymph

nary Dassages

3 Acute septi nephritis without surpuration an ascending septic lesion of the kidney without suppuration the virus being carned to the kilney (most commonly to the ortex) by the lymphatic

4 Pyelonephrus suppurative nephrus with the antecedent eptic diseases I th pelvis the second ary foci in the farenchyma of the kilney being always du t direct ontamination through the unniferous tubules and 1) my hattis.

5 Pyelitis suppurative disease of the mucous membrane of the pelvis without distention of the cavity

6 Iyonephrosis accumulation of pus or of purulent urine in the pel is of the kidney the a cumulation being a result of mechanical obstruction with atrophy of the renal tussue but with ut see nl ry infective foci or Indepen lent accumulations of ju in the parenchyma of the organ

In inflammation f the blailer the t o most requent sources of infection are the intestines and the urethra. Three modes finfection are enumerated.

Asc aling infection by way of the urethrawhich for ob rous reasons is more common in

women than in min it r sampl in gen ith galand colin bacilla infection

t. In a majority of cases the disease occurs, n the right side though it may be bilateral or limited to the left side.

Various speculations are advanced regarding the special influences exerted by pregnancy in causing pyelitis. Although it is possible for the pregnant uterus to so mould itself as t exert direct pressure on the ureters, we have absolutely no exact kn wledge as t th frequency or the degree of obstru tion to the flow of urine in the uret ra

Dilat tion of the ureters and renal pelvis may be found in pregnant women at autopsy or peration but the condition may have existed prio to preg nancy I terference with the ureters uch as is produced by pelvic tumors is comparatively rarely associated with pyelith Moreover in considerable percentage of cases of hydro-ureter pyelitus is found. In those cases in which there

is the greatest intra-abdominal pressure e.g. primiparity hydramnica, twin pregnancy turn is and pregnancy there is no greater tendency t pyelitis

than in other gestation cases.

As to the greater frequery of right-sided pyell tis without ureteral catherization no one is compe tent to judge whether one or both sides are affected as pain on e sid only is no proof that the other sid may not be affected. Nor does the pressure of the fline vessels explain it. Dentroversion or dextrotorsion hardly explain it either for unless there is a very lax abdominal wall no pocecuable movement of the pregnant uterus in dvanced pregnancy can tak place, and then it tends t fall for

ward when the woman is erect The greater mobility of the right kidney in on-pregnant women which leads to dilatation of the renal neivis may cause the development f pyelitis by micro-organisms. Colon bacilli are th most common organisms found in pyclitis. As to the mod f entrance of the organism the foll wing

views are held

From the vulve through the urethra, bladder and ureter probably rare.

Lymphati extension from infected bladder This is difficult to prove and must be rare

The most common source is undoubtedly the ge intestine, eithe by di ect lymphatic extensi n or by the blood stream

4. Distant focal infections especially those due t streptococci nd staphylococci may cause pye litis by blood transmission though definit proof

has not been established.

The symptoms and signs of the disease are the same as in non-pregnant women. In some uses the patient may complain only of malane and shight fever without pain. The fever may be high and may be companied by chills. There is often aching in the loins. Frequently attention is first called t a pain in the affected side accompanied by fever nauses vomiting In some cases there is frequency of urination Rarely is there actual bladder distress except where the viscus is involved. Right sided pyelitis may simulate appendicitis o

even gall-bladder disease, od serious mistakes i diagnosis may be worded if this is borne in mind. As t treatment Rest bed, soft pon-irritating diet free fluids and unnary antiseptics are most and ly emplayed and will suited for large percent age ficases. Autogenous color has been disanpointing Irrigation of the kidney pelvis through the cystoscope has also been unsatisf ctory

C. C. O'CROWLEY

Fernandes, J. Digital Compression of the Lach rymal Sac in Decryocystitis f the Newborn Especially La compression digital del saco lagramal en la darriocatith d l recien nacido especialmente) Res d med s 0 6 TTL 4

The a thor d ells on the value of massage of the sa in congenital dacryocystatis, polied co tinuously and by digit I pressure this being the simplest method of procedure.

Fully as satisfactory results ere obtained i the newborn as i the adult. The comp earlon

The pro-

of the lacrymal sac requires manual lettenty especially in cases of inflammations or ced mas in the proximity of the sac. In mono-ocular affections it is best to search for the rest of the lachrymal bone and press upon it immediately whereupon the lachrymal sac will move from that place in the fossa.

To determine the permeal dity of the navil and the author installs a drop of fluor scen solution. He believes in Berard's teaching that by comprose of the sac and antiseptic injections in thos. I have and parts previously did at Jone can properly treat and cure a case of darry ocystitis. We to catheter sation of the nasal canal the nuther noss liers it improper treatment he quotes Hippel state mut that the soun ling of the nail canal is not car your moderative, and the inexperienced will make 1 becomes which will give rise to new caterines.

The author describes the case of a habe 55 has old, in whom he noticed on the inteenth lay [life a dacryocystitis and an energialoid tumor both [which responded equally will to compression practiced continually for several months when the

two conditions disappeared entirely

He considers it unnecessary to recall that in the diagnosis of a deary-oxysitis in general h 1 fest thing to do is to ascertain whether the nasal nal is more or less free so that when the lacryoxy titt is relieved the tears yill fillow their nor all course.

Another case is described of a woman sufficing for two years with a suba ute daily yet titis in which compression and lavage of the silvought about a complete cure. A vera after however the patient having discontinuit which has firm time to time had another inflaimation of this Besides the employment of ompression the inflam fenor lacherymal point was dilated to facilitate the egress of all accumulations in the sa

The author considers digital impression very valuable as the initial treatment in general dicryo-cystils. When the condition is so a use and pain ful as to prohibit its use he ad uses applications of ice and abstention from making any incisions to avoid cicatiness upon the skin of the ey lids.

FAR

Good R II Acute Otitis Media. III II J

A bit if review is given of the ctiology symptoms inferential diagnosis and treatment prophyla tic local and general of acute offits media with the object of urging the general practitioner to make an early diagnosis and avoid unfortunate complications

The author insists upon the necessity f early diagnosis before the drum membrane ruptures and serious pathological changes have taken place in the tympanum. He advises early incusion of the drum membrane by an otologist under asceptic conditions and early operation in cases where mustood symptoms supervene together with proper general medical treatment. Which Oats Do You Advise?

A bushel of choice outs contunabout ten pounds of big plump luscious grains

The rest are little grains under ted puny and insipid

In Quaker Oats to get extra flavor we flake the queen grains only But we use the small grains in other ways So Quaker Oats costs no extra price to users

If you approve this plan please tell the facts to people you advise

Quaker Oats

Extra-Flavory Flakes

Quaker Oats dominates all the world over Even in the British Isles—the home of Scotch and Irish cats All because of the big white flakes and extra luscious flavor

> Regular Package 10c Except in Far West and South

Diphtheria Antitoxin Mulford

For the Treatment and Prevention of Diphtheria

Diphtheria Antitoxin has reduced the mortality of diphtheria from 40 per cent to less than 10 per cent.

This mortality may be still further reduced

By usua Diphtheria Antitoxin earlier

By giving larger doses 5000 to 10,000 units.

By intravenous injections in severe or late-treated cases.

The Time of Administering Authoria is Vital.—In the Philadelphia Hospital for Contagious Ducases, from 1904 to 1910, 256 diphtheria patients were treated on the first day of the disease and all recovered.

Patients treated on the second day the mortality was 5.4 per cent.

In those treated on and after the third day the mortality was much higher

The early administration of Antitoxin is imperative

Layer Doses in Necessery—The Object in administuring Diputtors have to be neutralized has alternated in such as a second of the substance of the period (form) circulating in the blood stream and tase 6 fluids. Dr William II Park advises 10,000 until In severe cases for bittle children, and 20,000 units in severe cases for ad its. This is practiced in many leading booptials

Intravenou Injection.— No case should be considered hopeless. I maignant cases shout by the intravenous use of

and late stages of diphtheris recovery may be brought about by the intravenous use of Antitoun in large doses. The Antitouth is thus carried directly into the circulation and its activity exerted at once, whereas, if given subcutaneously only one-tenth of the amount reaches the blood stream at the end of 4 hours.

The incorporation of Levia doses is supervisited than we consider the impossibility.

The importance of large doses is appreciated when we consider the impossibility of ascertaining the amount of torus circulating in the p tent's blood. The only safe rule is to give sufficient anticots. The giving of larger doses than are necessary does no harm; but an insufficient first dose and in some cases the lack of intravanous injection, may be serious mistakes.

Diphtheria Antitoxin Mulford is accurately standardized and repeatedly tasted. It is supplied in the Mulford scoptic antitoxin syringes, ready for immediate use containing 1000, 3000, 5000 and 10,000 units. 20,000 units supplied on special request.

Gas Oxygen Anesthesia and Analgesia

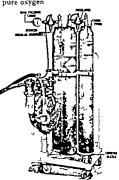

The McKesson Apparatus

These machines are designed and constructed by a physician who knows the requirements of an apparatus for Hospital Office and Home use. Every element leading to perfection has been carefulls, worked out in the operating room and embodied in the apparatus mechanically

To secure accuracy and constancy the patient is breathing automatic ally regulates the flow of gus and oxygen with each breath. All rebreathing is controlled by a graduated adjustable bag which also measures the size of the respiration and operates automatically. An emergency valve is provided for artificial respiration with pure oxygen.

The Junior is designed especially for Analysesal Obstetrics and psinful dressings, also for short anesthesiss in muor surgery. In its carry of case it weight only 15 lbs. trifle larger than microscope case.

HORPITAL UNIT NO. 60

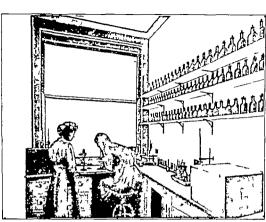

The Modal F is constructed in Portable, Office and Hospital types. Appropriate inhalers for every kind of operation including eye, ear nose and throat work are provided.

The Junior model is light, simple and automatic for analgesia, requiring no one with experience t adjust or regulate it. The patient betterlf can apply and remove the missk as directed by the obstetrician, and secure good esults.

Life Strike of Life to Const.

How is Surgery to be Taught?

You are interested in these questions Where can I get instruction and practice in surgical technique? How can I improve my technique? How long can I afford to be away from my practice?

For over a year the Laboratory of Surgical Technique of Chicago has been answering the above questions by satisfying practitioners from all over the United States and Canada.

They have worked out an original plan of teaching the technique of surgery that not only gives the man the in struction but allows him time to do the operations over and over until he is satisfied that he knows the technique

They have taken care of the busy surgeon as well as the practitioner whose experience has been more or less limited. Men realize that time is a factor in every operation and they want their technique improved so that they can get their patient off the table quicker

The laboratory is open daily from 8 to 5 o clock, which makes it possible for the man whose time away from his practice is limited to get the work in the shortest time cossible.

Aid No. 1. The Art of Diagnosis

Have you ever taken a few minutes off to analyze your own ability or weakness as a Diagnostician? Have you considered what it means to be a Good Diagnostician measured in Prestide and ultimately in Dollars and Cents?

THERE never was a time in the history of the profession when more attention was being devoted to the art of diagnosis. The men with whom the practitioner must measure arms on the morrow are taking up the practice of medicine with a better knowledge of the means and methods of diagnosis than it was the fortune of the men of a generation ago to possess. It is said that today less than firty per cent of the dangoois made during life tally with the conditions found on necessary. Yet there is hardly a practitioner in the country who can take time from his work for post-graduate trisining in more up-to-chat diagnostic methods

What About an Investment in Reliable Literature on Diagnosis?

*HIS book is a groundwork upon which the student interne and general practitioner may acquire a more comprehensive knowledge of the 'Art of Amesthesia. A bird s-eye view of the entire field of amesthesia is given by defining and describing general local and mixed amesthesia. General amesthesia is taken up in detail.

Ether anesthesia, oral insuffiation intrapharyogeal insuffiation intratracheal insuffiation rectal and intravenous methods, are followed by general anesthesia by ethyl chloride, chloroform introns order introduced by the control of the control of the control of the control of the control of the control of the control of the general practitioner a chapter on energency anesthesia has been prepared. Bearing in mind the needs of the general practitioner a chapter on energency anesthesia has been prepared.

Most thoroughly and practically illustrated and moderately priced.

ROBERTS AND KELLY

FRACTURES

By JOHN B ROBERTS M.D. F.A.C.S., Professor of Surgery is the Philadelphia Polyellaic

TAMES M KELLY AM M.D. Amonate in Surgery in the Philadelphia Polyclinic

Octavo 677 pages

909 Illustrations.

Cloth \$6.00

ONG hospital training observation in America and Europe and undergraduate and postgraduate actions have fitted the authors to produce a book acceptable to experienced practitioners. Statistics normal anatomy pathology the types of fracture complications, methods of treatment and results are included in the discussion of each region of the body

By a great number of \(\text{ray} \) plates are indicated the types of injury met in the different bones and by

the side of these are placed illustrations of original drawings shown in the muscular attachments by which the usual deformity of the limb is caused. The need for treatment of the soft parts in fractures has been

The management of these injuries by the early mobilization and massage methods of Lucas Championnière, and the tractio applia ces of Bardenheuer are discussed. The necessity of recognizing muscular contraction and of providing against displacement through particular muscular attachments is insisted

Lane a plating method. Albee a autogenetic inlay procedure. Stellamann a suggestion for nail extension and other direct methods of restoring skeletal integrity are discussed.

SHEARS

OBSTETRICS

By GEORGE PEASLEE SHEARS M.D. Professor of Obstetrics, New York Polyclinic Medical School and Hospital

Octavo 745 pages. 4f9 Illustrations.

Cloth \$6 00

R. SHEARS' originality both in his viewpoint and in his methods is the result of a very wide private a d hospital experience, in which he formed and corroborated his own opinious. In other words, the book is a laboratory rather than a library product

The same care has been applied in selecting the illustrations, which are designed to illustrate rather than to ornament the book.

Dr Shears has written his book from the practical rather than from the purely academic standpoint and has laid emphasis upon the fact that not every practitioner has at his disposal the facilities of a hospital or clinic and while the methods advocated in the book are thorough and up-to-date Dr Shears has aimed to present them in such a way as to require the least complicated apparatus.

Many common sense hats n t usually met with n works of the kind are of inestimable valu for the welfare and comfort of the patient.

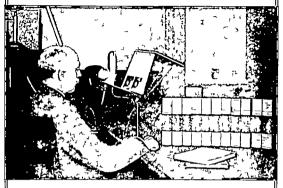

The author ha shown that it is quite possible to be exhaustine without being exhausting

THE ETIOLOGY AND PATHOLOGY OF NON TUBERCULOUS RENAL INFECTIONS¹

By HUGH CABOT M D BOSTON

Assertant Professor of Genito-Urinary Surgery H. rvard Medical School and Clard of Genit. Urinary Department: Massachusetts. General Hospital

E. GRANVILLE CRABTREE M D BATON

Assertant in Grant Urmany surgery Harvird M. Incal School and Assertant Genuto-Urmany Surgeon Out P twot Department Massachusetts General Hospit d

THILE it is almost literally true that a satisfactory comprehension of the diseases of the genitourmary tract depends upon a clear appreciation of the nature and probable course of renal infection there is no subject in which there is so little uniformity of opinion and so The literature of the submuch confusion sect is stupefying both in quantity and in complexity and anyone who has attempted to master it will we think be convinced of the fact that it is more likely to confound than to enlighten the reader. Not a little of the confusion arises from a somewhat inaccurate use of terms. Thus the great majority of writers using the term ascending renal in fection mean a process which ascends from the lower to the upper urmary tract, but Mal lory has for some reason seen fit to use the term to mean ascension from the renal pelvis into the kidney substance and has confused without enlightening. The phrases static, embolic, hæmatogenous bloodborn have been used with a looseness which defies comprehension and finally the persistent description of various stages in the same process as different pathological entities has rendered confusion worse confounded Not

the least serious difficulty has arisen in the almost entire failure of collaboration between the clinician and the pathologist years ago Orth showed a very interesting under tanding of the ctiology of renal infections which the clinicians have apparently largely overlooked. On the other hand as in the ancient history of renal tuberculosis the pathologist has wrought havoc with an under standing of this subject because his opinions have been based considerably upon post mortem material which it might be sug gested is likely to represent fatal cases and has therefore jumped to the conclusion that a given type of lesion is generally bilateral whereas in fact it is bilateral only in the fatal cases

A more or less intimate association with the subject of these infections early impressed us with the completity of the picture which may be presented by kidneys which are the site of long standing infection. It is not rare to find kidneys showing the evidences of at least three infections differing in point of time and often in the nature of the organism in volved. That these should present to the pathologist a situation almost too complicated for satisfactory solution is not surprising and

we have come to believe that many of them can be interpreted only in the light of considerable knowledge of the clinical history coupled with great familiarity with renal pathology. In the attempt to solve the intricate problems of renal infections much assistance has been rendered by the use of animal experimentation and vet it has in some hands led to wholly erroneous conclusions which have done considerable damage the error ansing very largely from the at tempt to draw conclusions from the effect upon animals of organisms whose behavior is very different from that which they exhibit in the human body Thus, the colon bacillus rarely produces suppurative lesions of the kidney in man while in animals it may readily do so and this has given rise to the mute erroneous assertion that the colon bacal his commonly or even regularly produces abscesses of the kidney. Where so much turns upon the exact nature of the levon produced a study of the lesions in animals must be surrounded with every precaution, if the conclusions are to have validity experience has led us to the conclusion that it is wholly unsafe to use the same organisms commonly found in human renal infections in carrying out animal experiments and we incline to the view that the safest procedure is to select organisms which produce similar lesions in other organs and reason from parallel rather than from identical lesions. In studying this subject we have come to regard it as important to consider the lesions produced by various organisms upon kidneys previously normal, in order to get a clear understanding. It has seemed to us that in the past, attempts to explain the lesions produced by infection upon kidneys previous ly damaged has been a potent source of error and that an understanding of the lesions found under these conditions is most likely to come through a study of the lesions produced in previously healthy kidneys. There fore, in discussing the subject we have divided the field of renal infections into two groups Group I, including only those kid nevs which were previously normal as far as the clinical evidence will permit of a decision. and Group II those in which infection was

grafted upon some other lesion of the kid ney such as stone tumor or dilatation due to obstruction.

BACTERIA CIRCULATE IN THE BLOOD AND ARE EXCRETED BY THE KIDNEY WITHOUT PRODUCING GROSS LESIONS

Many years ago various observers includ ing Hoffman Rochrig Maas Wiener Ruti meyer and Cohnheim showed that insoluble substances such as claushar and fat could be made to mas through the healthy kidney Particles of these substances were found in the capsule of the glomerulus in the tubules, and in the urine In 1806 Biedl and Kraus showed that the staphylococcus aureus the becillus coli and the anthrax becillus passed through the healthy kidney. The same fact was demonstrated for the typhoid bacillus by Larmiere and Abrami by Roysing for the bacallus coli by Cuturi for the same or ganism and by Patrick for various organisms in the course of typhoid fever Meyer Walschmann Heyer Kramer Buday Wyssokowitsch Rolly Brown and Cunningham have shown that in the course of tuberculous leaons elsewhere in the body tubercle bacilli appear in the urine at various times and in varying quantities without any evidence of damage to the Lidney Honen has made a similar observation for the bacillus of leprosy In this connection should be mentioned an interesting series of observations noted by Swart and Craig that, following the administration of salvarsan to nationts with lenross or patients with tuberculosis, the bacilli appear in the urine in large numbers and the course of the disease is often unfavorably affected On the other hand Wyssokowitsch in 1886 experimenting with a variety of pathogenic bacteria including the pneumococcus the typhoid bacillus anthrax bacillus, and the staphylococcus aureus found them appearing in the urine with evidence of the production of kidney lexions. Similar conclusions were drawn by Cocordi in 1888 Pernice and Scarling in 1802 Sherrington in 1803 Cotton in 1805 and Jahn in 1910 This array of apparently con flicting testimony has brought certain eminent observers to the conclusion that in the cases

where no lesion was discovered it was because a slight lesion had been overlooked we believe to be an entirely unwarranted conclusion. In view of the fact that insoluble substances have been shown to pass the Lid nevs without damage in view of the fact that many competent observers have passed bacteria through the kidney repeatedly and then examined these kidneys after sacrifice of the animal, and in view of the fact that we are daily accepting the clinical evidence obtained by the study of patients in regard to the integrity of their Lidneys we cannot avoid the conclusion that bacteria pass the healthy That they do not do so always or under all conditions simply confirms the well known fact that local conditions in the kidney and general conditions in the organism influ ence the occurrence or non occurrence of infections. While we are prepared to admit the accuracy of all the observations above quoted they seem to us to prove conclusively that organisms circulate in the blood and pass through the kidney in many cases without producing any lesion and in many other cases with the production of various lesions

BACTERIA CIRCULATE IN THE BLOOD AND ARE EXCRETED THROUGH THE KIDNEYS WITH LESIONS MILD OR SEVERE

In 1915 Kowitz studying a group of chil dren with infectious diarrhæa found the following sequence of events in tive cases

Blood cultures showed the bacculus colt Promptly thereafter there appeared in the urine first albumin then bacteria and finally pus Exploration of the records of the medical services at the Massachusetts General Hospital has yielded us an interesting series of 8 cases of bacillemia and bacilluria which it may be noted occurred entirely in women They entered the hospital with the diagnosis of fever of unknown origin

CASE I Woman age 35 Blood ulture showed bacillus coli urine profuse growth of the same organism. I hysical examination negative except for elevation of pulse and temperature. Recovery

CASE Woman age 20 Physical ramination negative Temperature 103 Pulse 10 Widal negative Blood culture unknown bacillus unne bacillus coli stool persistently negative for typho disacilli

CASE 3 Woman age o Entrance diagnosis paratyphoid Blood culture banillus coli urine culture colon like bacilli Recovery

CASE 4 Woman age 23 Siter of Case 3 Entrance diagnosis paraty hold Blood cultures lost urine culture basillus oli Recovery

CASE Woman age to Entrance diagnosis question of typh id. Blood cultur's proving growth colon bacillus bladder unne colon bacillus right ureter colon ba'llus left ureter no growth. Per sist nt right byelitis.

CASE 6 Woman age 35 Entrance liagnosis unknown fever Temperature 102 Pulse 95 Blood culture colon bacillu urine culture colon bacillus Recoveré

CASE 7 Woman age 2 Entrance diagnosus a ute infection Temperature 100 5 Pulse 08 Blood culture motile bacillus (bacillus paraty pboid?) urine bacillus coli Death in on week No autorox

CASE 8 Woman age 62 Entrance diagnoss convulsions Temperature to Pulse 110 Blood culture colon like bacilli urine culture colon like bacilli Death in one week Autopsy calculus progenyiosis bulateral suppurative nephritis

This group of cases is interesting from several points of view. Most of them were regarded as cases of probable typhoid and attention was particularly directed to this condition. Their blood however failed to show a Widal or to react to cultures of the paratyphoid bacillus and they were finally proved to be due to the other member of this group the colon bacillus. We believe that these cases simulating typhoid and due in fact to the colon bacillus in other words cases of colon bacıllus bacıllæmıa are much more common than has been generally supposed The records of any large hospital during recent years will show a considerable number of these cases in which clinical symp toms suggested typhoid but the diagnosis could not be confirmed and they were finally discharged cured often with a diagnosis of paratyphoid. A correct solution can be obtained only by careful study of the blood and urine with good technique, and particular. ly when they are seen at an early stage of the disease

That the colon bacillus can be obtained from the blood in cases of acute pyelonephrits with considerable frequency has recently been shown by one of us $(E \cup C)$ who in a sense of 32 cases obtained positive blood cultures in 40 per cent a ratio larger than that

ordinarily obtainable in typhoid fever which is admitted to be a bacillemia. One case occurring under our observation and carefully studied throws considerable light upon the natural history of this process

The patient was a man of ec with benish enlarge ment of the prostate sland and residual urine. Cultures controlled by stained sediment showed the urine free from infection at entrance to the hospital. He was immediately placed upon constant drainage with an inlying catheter Cultures from the blad der urine were taken the evening of the seventh day up to which time he had complained of no symptoms whatever These were sterile. At eleven o'clock of the eighth day be complained of a burning sense tion in the urethra and two hours later had chill and sudden sharp rise in temperature. Blood cultures were taken two and one half hours from the beginning of ymptoms of prostatic irritation and one-half hour after the appearance of the chill and rise of temperature. A pure growth of colon bacilli was obtained. Centrifuged urine obtained from the bladder at the time the blood culture was taken showed no bacteria in stained sediment. Cultures taken from the bladder urine the following morning showed an abundant growth of colon bacilli. Pus was present in very small amount. The renal functional test with phenolalphonephthalein show ed a drop in 24 hours of 20 points. The patient complained of right-skied costovertebral tenderness and headache and presented the usual symptom complex commonly called pyelitis, which we believe to be a pyclonephritis. He was allowed to remain on constant drainage for a week longer dur ing which time his phthalein output returned to within five points of its former level. Perineal prostatectomy was then done. The patient made an uneventful recovery until the ninth day when he bled. The wound was packed and bleeding controlled. The temperature rose and the patient died. Necropsy showed anemia and streptococcus septicemia. The kidneys were pale with normal markings and little, if any dilatation of the pelvis (Fig A) They were passed by the pathologist as normal kidneys.

This case clearly shown haddlemia, badl luria, pyelitis and pyelonephritis. The endence of pyelonephritis is based chiefly upon the sudden great drop in kilney function which we think may be taken as evidence of acute cloudy swelling of the kilney probably involving chiefly the tubular portion. That this process is short-lived and goes on rapidly to practically complete recovery is suggested by the return of kilney function and conclusively proved by the appearance of the kilney post mortem.

Finally in support of the above mentioned proposition we submit the results of the in oculation of a rabbit with the paratyphoid bacillus alpha. It should be remembered that the paratyphoid bacallus has for rabbits a pathogenicity quite similar to that shown by the colon bacillus in man. The cultures used in this experiment were three year old cultures. At the beginning of the experiment the bladder urine was shown to be sterile. An emulsion of the organisms, about a cubic centimeters in amount was introduced into the car vein on three senarate occasions during a period of five weeks. Following each injection the organisms appeared in the urine promptly and in enormous numbers. Five days following the last injection the animal was sacrificed Sections of the kid nevs carefully studied showed practically no lesion and were certainly within normal limits for laboratory animals (Fig. B)

ASCENDING INFECTION BY WAY OF THE

The theory that infections reach the kidney by direct extension from the lower urbary possages has acquired the dignity associated with old age and has been a widely held and attractive theory because of its extreme and tomic simplicity. We believe that it can be shown that its simplicity is apparent rather than real, that most of the cases in which it has been supposed to occur were based upon a complete misconception of the facts and that this method must in reality be regarded as exceptional. It has been customary to assume that in this method of real infection the bacteria reached the kidney by one of

- By continuity from a bladder infection by direct extension of the process within the humen of the ureter
- 2 By the transportation of the bacteria in a column of urine which is supposed to exist within the ureter. By this conception the bacteria float upward, apparently in pelled also by their own motive power in contemptuous disregard of the descending stream of urine and ureteral peristation.
- 3 By reverse peristalsis within the ureter This, of course presupposes obstruction of

the ureter since as far as we know there is no warrant for the assumption of reverse period stalisis in the absence of obstruction. That reverse peristalisis occurs in the presence of obstruction we believe to be a dimonstrated fact the best evidence of which in our personal experience has been the movement of uretural calculi from the kidney to the lower end of the ureter and then back again a journey which could hardly be expected to take place under any force other than reverse peristalisis.

The whole theory of ascending intection rests primarily upon the proposition that in fection of the bladder takes place under a great variety of conditions una sociated either with trauma or with retention for unless a pre-existing cystum is assumed the whole proposition falls to the ground as applied to a great mainty of the cases

More than a quarter of a century ago Rov sing and Melchior showed that (a) experimentally cystitis could not be produced in animals without retention or trauma that (b) with retention of urine experimentally produced there generally resulted no pichits that (c) trauma to the bladder with or without retention produced pichits and pichionephints. In passing it should be noted that in these later cases sections of the bladder wall showed extensive hemorrhage with bacteria in the blood and lymph channels an observation the importance of which will later appear.

Baueret.en concerning himself wholly with the lessons produced by the tubercle bacillus drew three conclusions (r) A bladder with intact mucosa cannot be infected (2) With the flow of urine unhindered tubercle bacilli cannot reach the kidney through the ureter (3) Obstruction of the urnary stream will as a rule result in urogenous ascending in fection of the kidney. This last conclusion implies a dilatation of the ureter and an in competent urcterovesical valve

Draper and Braasch in a very thorough piece of work in which they attempted to produce ascending renal infections wholly failed to do so except by maintaining an abnormal amount of pressure in the bladder over a long penod of time

It thus appears that the experimental work

wholly fails to support the assumption of ascending infection by means of the urinary passages. When produced as by Roysing and Mckhior there i no warrant for the assumption that it ascended since the blood and lymph channels were shown to contain busteria and it is far more probable that the bacteria reached the kidneys by one or both of these routes It is notorious that bacteria in the bladder, whether introduced from above or from below ful over a long period of time t) produce lesion There is a mass of clinical evidence showing that tuborcle bacillicoming from an infected kidney will pals for years through the bladder without producing a lean Of late years when the cystoscope and prefer catheter have made accurate diagnosis of conditions in the upper urinary tract possible a multitude of observation have been recorded of colon bacillus pyelitis and pyclonephritis from which the colon bacillus passed to and through the bladder for years without producing a lesion

A recent communication by Hess in which he described the result of investigations of the bacteriology of bladder immediately following cystoscopy throws considerable light upon this question. He showed that in the first days following instrumentation bacteria of various kinds could be found in the bladder with regularity that they produced neither the symptoms nor the sign of cystitis and that in a few days they disanpeared We have become wholly accustomed to regarding the cystoscopic examination of the bladder under normal conditions as a harmless procedure. If these observations of Hess be confirmed it show that the harm lessness consists not in the ascritic character of our procedure but in the vitality of the vesical mucous membrine and its ability to shake off the milder degrees of infection

We do not intend to convey the impression that we believe that ascending infection from the lower to the upper urinary tract must be wholly discarded for there are two conditions under which it is theoretically possible and practically probable. The first of these is ureteral obstruction which may theoretically be of three types that due to stone that due to inflammatory stricture and that produced

by the abnormal constriction of the lower end of the ureter by hypertrophy of the bladder such as is seen in diverticulum, in tuberculosis and in obstructive conditions at or below the neck of the bladder In hollow viscera else where in the body obstruction is followed by reverse peristals with singular regularity and it is but reasonable to assume that the ureter a hollow muscular organ behaves in a similar fashion Further warrant is given to this belief by the observation in regard to stone in the ureter above referred to Now under conditions of reverse peristalsis bladder in fection with extension by direct continuity to the lowest portion of the ureter would give rise to conditions highly favorable to renal infection if assisted by reverse peristalsis. The other condition clearly opening the way to ascending infection is incompetence of the ureterovesical sphincter such as undoubtedly exists in a certain number of cases of obstruc tion at or below the vesical outlet. In these cases the dilatation has become so extreme that the renal pelvis is for all practical pur poses in direct open communication with the bladder cavity and any condition existing in the latter will promptly be communicated to the former by the simple method of back wash Under these dreumstances, if the kidney is not already infected it will promptly become so

The pyelitis, so called, of pregnancy and the equally improperly termed pyeliths of childhood have been the great strongholds of the ascending infectionists. Their theory has been based chiefly on anatomical fact unsupported by clinical or experimental evidence The short urethra and the comnarative ease with which the region of the urinary meatus might be contaminated with the colon bacillus, together with the fact that in the adult female vesical irritability is often the first thing to attract attention, have been the two important premises. It has not been shown that the cystitis antedates the pyelitis, for the good and sufficient reason that such is rarely the case. Furthermore should it be shown that the cystitis was pri mary there is no basis either in man or normals for the assumption that with neither retention nor trauma a cension could occur

The fact that this disease occurs with far greater frequency in the female whether child or adult is important but its significance has been wholly misunderstood. It is interesting to note that in the eight cases re ported above of proved bacillemia and bacil luria all were women. In the adult female, we think there can be no doubt that the conditions normally existing in the large in testine are more favorable to the occurrence of bacillamia than in the male as yet no adequate explanation of the greater frequency of these infections in the female child but we think that existing evidence points to the view that this explanation will be found not in the anatomical peculiarities of the female wrethru, but in the anatomical peculiarities of the female intestine

ASCENDING INFECTION BY THE LYMPHATICS

For many years occasional observers have called attention to the possibility that bac teria might reach the kidney by way of the lymphatics. It has perhaps been most extensively discussed in connection with renal tuberculous but of late years the discussion has been extended to include other organisms and a variety of publications showing careful anatomical study have tended to support the theoretical contentions.

Mascagni showed that the lymphatics of the upper reter drained into the lymphatic syst m in the region of the kidney pelvas and that organism might reach the kidney along these channels. H also showed that the lymphatics of the I were ureter drained into the lymph nodes of th anat mical neight.

Saksta confirmed the above bervations c of thribe showed that the system of lymphatics of the upper unter and the system of lymphatics of the upper unter and bladder are on onected by an intermediat chain of lymphatics embracing the entural portion of the ureter. It is easy however to exaggerst the importance of this observation slacer Saksta work howe that this chall is of continuous, b t is, on the contrary highly interrupted. Organisms in order to extend from bladder to kidney by this route would he et pass through several systems of lymph-nodes, contingency which importantly decreases the probability of uch an occurrence.

Surimura at died series of cases and showed that in the presence of cute cystitis the lower third of the ureter was constantly in olved, pparently through the medium of the lymphatics. If drew this conclusion because there was very slight in volvement of the mucous membrane of the lower ureter while the lymph-channels of the muscularis and adventitia were extensively involved

Francke has shown a lymphatic communication between the right kidney capsule and the adjacent

ascending colon

kumala has demonstrated a system of superficial and deep lymphatics in the fatty capsule of the kidd ney. This system apparently drains away from the kidney communicating with the subdisphrugmatic lymphatics.

A recent paper by Lisendrath states his belief that he has d monstrated that bacteria ascend by the lymphatics from the bladder to the kidney and produce renal infection. After a careful study of this paper we regret that we are entirely unable to follow him to his conclusion. The method by which the lessons were produced it nowhere stated. The lessons are not strikingly different from those which are found in blood born infections and finally the evidence which he submits of the lessons of the kidney is so meager and differs in such important particulars from the infectious lesions ordinarily found in the kidney that we must question their similarity.

Upon the framework of the above men tioned anatomical observations several writers have attempted to crect a theory of lymphog enous infection of the Lidney Though the framework is valid in its individual members the complete structure seems to us frail and It is generally believed and upon sufficient evidence that the lymphatic currents throughout the body follow the flow of blood in the blood vessels. Unless we are prepared to disregard this doctrine it will be difficult to trace lymphatic processes over areas which are totally lacking in continuous vascular channels. Now there are no blood vessels running an uninterrupted course from the bladder to the Lidney The blood supply of the ureter is distinctively segmental and the only vessels which run in this general direction are the spermatic vessels in the male and the ovarian vessels in the female run in different sheaths and would be with difficulty accessible to organisms passing out ward from the bladder Furthermore assuming the probable fact that organisms reach the lymphatics about the bladder and over the lower segment of the ureter the probability of their reaching the blood stream rather than continuing in devious lymphatic channels seems to us overwhelming

organisms pass from the bladder into the perivesical lymphatics reach the blood stream and ultimately the kidney we not only believe but are prepared to show and this possibility must always be reckoned with Reasoning from lesion produced by lymphatic infections elsewhere in the body progress by this method is comparatively slow and on account of the interrupting lymph nodes is more likely to produce highly local ized lesions than lesions spreading rapidly over long distances and flooding a distant area with organism

Finally the evidence of the lesions actually produced in urinary tuberculosis is enlighten It is generally recognized that the involvement of the urcter is earliest and most marked at its two extremities and it is not uncommon to find a central portion of the urcter wholly or comparatively free from tubercular disease. Those who have regarded the work of Francke concerning the lymphatic communication between ascending colon and the right kidney as conclusive seem to us to be reasoning upon insecure premises Arbuter shown that when organisms leave the intesting by the lymphatics they rapidly appear in the blood and this tendency is amply confirmed by a large series of observations which concern themselves not only with the migration of bacteria of the intestine into the lymphatics but with the ways in which foreign proteids leave the intestine under abnormal conditions

Thele and Embleton have shown that after pentoneal infections the organisms rapidly reach the blood stream and are excreted by the normal kidney. If however the thoracic duct be opened so that bacteria can escape no such excretion occurs.

If for a moment we disregard the large probability that bacteria leaving the in testine by the lymphatics will reach the blood stream rather than the kidney we must yet believe that a lesion of the kidney thus produced would in all probability be a localized lesion rather than a widespread diffuse lesion such as is notomously produced by bacteria of intestinal origin

See author's case p. cl.

WHY ASSUME THAT COCCI GENERALLY REACH THE KIDNEY BY THE HEMATOGENOUS ROUTE, WHILE ASSUMING THAT COLON BACILLI GENERALLY REACH THE KIDNEY BY ASCENSION FROM THE BLADDER?

It has been long assumed and following the work of Brewer has been almost universally admitted that the staphylococcus infections of the kidney are of hematogenous origin. These infections have been shown to be associated with furunculosis carbuncle, and various septic foci elsewhere in the body The identity of the organisms in both places and the impossibility of sustaining any assumption of transference other than the blood has led to these lesions being regarded not only as harmstogenous lesions but the proposition has been even reversed and the hæmatogenous lesion has become almost synonymous with coccus infections. On the other hand the injection of the kidney with the colon bacillus, of which the purest types are the pyelonephritis of infancy and pres nancy has been regarded as ascending chiefly because of the delightful simplicity of the assumption. If however one inquires as to the evidence of the hæmatogenous origin of both these types of infection one is at once struck by the fact that the hematogenous onem of colon bacillus infections has been demonstrated beyond the shadow of a doubt. the organisms having been repeatedly found in the blood and subsequently in the urine while as far as we are aware there are but few cases on record in which the coca con cerned in the so-called harmatogenous coccus infection of the kidney has been captured during his journey through the blood While this should not be taken as in any way tending to invalidate the harmatogenous origin of the coccus lesion at seems to us to at once put unon the defensive those who would assume that colon bacillus infections of the kidney are produced by any method other than the hamatogenous one. At least as far as con cerns the pyclonephritis of the group above referred to we shall later submit evidence which seems to us to show that they can be produced only by organisms reaching the kidney through the blood stream and that the theory of ascension is wholly mythical

POSSIBLE SOURCES OF CONFUSION IN PREVIOUS STUDIES OF RENAL INSECTION

That the literature of renal infections is both confusing and confused in one who has attempted to digest it is likely to deny. There appear to us to be two chief sources of this confusion first a considerable lack of uniformity in the use of terms which at times amounts to a use so loose a to be positively midealing and second an attempt to study compleated and mixed 1-youn which are likely to dimest defe applysis.

r At the outset, there' re of the discussion of our own inclings we lestive to state clearly our understanding of the terms emboli metastatic, increasing of the terms emboli metastatic, increasing as applied to renal infection

A suppurative leaked of the kidney we regard a smile! ℓ when a definite mbolus shown to contain micro-organisms has bee dem instruced in a blood-vessel at the spex of the leased. This term has act think frequently been used: cover in encous kisons which were in no prope sense emboli in character.

A measuratic legion of the k direy w understand to mean supputati lesso produced by an organisati of the same character as one co cerned in a demonstrable suppurat it lesson elsewhere in the body.

The term kematagen as w hold to mean simply that the organizar rends the kidney by the blood. An context leave as ne produced d ring th process of exerct on of organisms by the kidney. It will thus be seen that the terms hemstogenous and excretory over very nearly the same ground Clearly no exerct presents can occur unless the process of the context process of the context process of the context process of the context produce when the produce are described on the context produce produce mbod very generally do produce exerctory lealous.

Lymphegenous covers all the uppurative processes, demonstrated t be prod ced l th ladney by bacters which has a strived solely via the lymphatics. And finally assend sig infection in the abused term, who do to mean the direct ascension of organ

term, we must be mean the direct ascention of organ hims from bladder t kilney by the humen of the uneter. This process may incl de either a direct extension stong a mucous membrane or a direct transference from bladder to kidney with the urine as vehicle.

2 We believe that a comprehension of renal infections is very much simplified if they be separated into two main groups Group I including all those infections of the kidney which occur in an organ previously sound and Croup II those infections which occur in a kidney previously unsound such as those damaged by stone tumor obstruction or chrone nephrits

A classification of the infections occurring in Group I has seemed to us after a not in considerable experience to be comparatively simple. We have a a rule been able to come to a satisfactory conclusion as to the cause and nature of the process and to arrange the lesions in an orderly and comprehensible fashion. On the other hand, there have been many cases falling under the classification of Group II in which the complication of lesions of variou dates and of essentially different pathological characteristics was such as to largely defy satisfactory explanation. For example a kidney long the resting place of a stone may show a variety of practically healed lesions the original nature of which must be permanently in doubt. Coupled with these may be two or even three more recent infection overlapping each other in position and perhaps in point of time and giving a picture so confusing as to be quite be vond us It may well be that a more ex tensive study of the cases in Group I will enable one to make a fairly accurate guess as to the probable cause of the various lesions of such a kidney as above described

A STUDY OF THE LESIONS ACTUALLY FOUND IN

For this study we have utilized a group of 118 cases classified as suppurative nephritis. These include both cases studied at autopsy and specimens obtained at operation so that we have not been confined to one particular type of material. Of these 118 cases we have been obliged to discard 58 either because they represented material obtained at autopsies done several years ago from which the paraffin blocks had been lost or the lesions were too chronic and too complicated to lend thurselves satisfactorily to classification or finally those in which we were unable

to demon trate bacteria. There thus re mains a group of 60 cases divided as follows.

- 23 were caused by and were demonstrated to contain staphylococci alone
- a treptococci ilone
- staphylococci and streptococci
- 25 were demonstrated to contain mixed cocci and bacilli
 - rg of these howed taphylocici in l
 - 4 howed treptococci and bacilli
 - 2 howed taphylococci streptococci and bacilli
- 5 showed bacilli only -

the bacillus coli and

the bacillus coli and another bacillu clearly a pyogenic organi m

I EVIDENCE OF THE PRODUCTION OF LESION DURING THE PROCESS OF FNORETION OF BACTERIA

The east for the proposition we clearly stated by J. W. Thomson Walker in his work on Surgical Diseases and Injuries of the Centle-Unitary Organs p. 120

It is now recognized that bacteria are "onstantly entering the lymphatics from the intestine and other sources in healthy individuals. The bacteria may be destroyed at the point of entry or at the lymphatic system into the blood stream in which they circulate. The endothelium and cells of the liver destroy

late I are endotherium and cells of the five destroy bacteria which are introduced by way of the portal system and bacteria are excreted in the bile. Simi larly a function of the renal parenchyma especially of the convoluted tubules. Is to remove the bactural present in the systemic circulation.

It has been proved that the virulence of these bacterns is not reduced in their passage through the body. The excretion of bacterns in this way does not give rise to any symptoms which show that the kind neys are damaged. It is stated however as the result of experiments on animals, that the secreting membrane is injured by the passage of the bacterns. The damage is probably slight and is repaired partly or completely by the regenerative powers of the kidney. In some cases long-continued exerction of bacterns or their toxins may be the cause of patches of intensitual nephritis in the kidney.

It is held that the exerction of bacteria locs not cause pyclonephritis unless some additional factor is present. Predisposing causes of pyclonephritis are traumatism excessive functional activity, the chimination of toxic bod es such as cantharides previous disease of the kline, such as urbary obstruct on calculus, new growth. It is exceptional

I all the following case report prior description and macroscopical seminations of sections in one of rises. In strong protection AD I II Wright and Dr. Obert Richardson. When spreasance from operations are seen the allow descriptions are operationed by Dr. Witters and D. Hart ell of he it been only of being supposed pathology department. When more detailed observations has in possible as routine ork ere required bey are given swifer he heading of sections, stands for headers.

however t find any of these factors present nd it is more likely that chronic toxicials from constipation, an excessive dose and an exceptionally virulent strain of bacteria, are the declaive factors.

It was also dearly stated by Orth in 1893

The question of the method by which bacteria reach the tubules in the pyramidal zones can, is my opinion, only be explained by axuming their passage from the blood into the capsule of the gi merula and their being carried along into the collecting tubules with the urine where they group together become arreach, and continue to grow

We append three cases which seem to us to clearly support the doctrines thus laid down.

CARE I Autopey No 3539 West Medical, 205300. Female, age 56 November 5 10 5 Diagnosis diabetes mellitus. Past history negative save for present symptoms which present four years ago Present illness - only sympt ms are those of diabetes. Physical examination negative as regards urinary tract. Patient was made and kept snear free with great difficulty and lost weight and strength under the treatment. U ine exemi elien at entrance showed sugar 7.8 per cent diaceti acid and acetone no albumin occasional pus-cell. Urine examination January 14 015, showed traces of albumin but scanty sediment containing only a few cells no sugar Temperature remained normal to subnormal from entrance t Ja nary o when it suddenly became a swinging septi temperature ranging from normal t or Blood cultures were negative whit count never above 9000. Renal function phthalein fell to 15 per cent for two hours. Death attributed clinically t acidosis and terminal infection. Cli ical di gu su diabetes mellitus. Terminal infection.

Autors of hour post mortem. Instantial diagram diabetes mellitus. Lokar posumodia, acute pleunità with effusion, arterisoelerosis fibremata of uterus, throude pertirodits and chromaspingitis, chronic intersitial pepartitis, chronic intersitial papularia myonicare, colon bardillas and sureptococcus septicemia.

Aidneys much enlarged Combined weight 558 grams Capsules strip leaving a pale brownish red smooth surface On section the tissue is swollen

but markings are related. The cortex is not narrowed. The cort is nep pal brown red with a slight purplish of red the appropriate the region of the appropriate the pale velowish opaque mooth discrete and on fluent streaks. The glomerult show no definite prominence. The pelves show injection of the blood vessels with minute red is spots. The unreturn and bladd rear normal.

Mar son examitation Throughout the whole tissue there is marked redemn. The corti al por tions of the kidney show normal glomeruli with some congestion of the blood years is and the great ma jointy of the ortical tubules free from pus but the pithelium shows cloudy swelling. In one portion of the kidney there is an an a of ext not e infiltration and necrosis of all renal tissue cyt inding transversely a ross a pertion of one of the pyramids. In this area the tul-ular epithelium is necrotiblood vessels are ruptured and the portion of the pyramid beyond is an emic. Above the area of necrosis the blood vessels are congested. In the remaining pyramids there are time treaks of poly morphonu lear infiltration extending from the bases of the pyrami is toward the apex (Fig. 7) In the least extensive of these processes the lumen of the tubule is seen to contain clumps of batteria surrounding whi has a lozeng shaped area of necrosis in luding the epithelium of the tubul and the interstitial tissue on each side sometimes extending far enough to include the adjacent tubule on each side Beyond this area is a border of pus-cell in filtration Occasionally throughout the cortical remons there are a few tubules ontuning pus-cells

Bacteriology at report. Cultures from the spleen show profuse growth of streptococci and question bacilli cultures from the heart blood show profuse growth of streptococcus.

Sections stained for bacteria show a few streptococci and bacilli without attending suppurative processes in the glomeruli and tubules of the cortex. In some instances considerable numbers of these organisms are found in the tubules containing the pus-cells previously described (Fig 8) In the area of transverse lesson of a portion of a pyramid previously described the tubules at the level of the necrotic area are found in many cases almost "om pletely destroyed yet the portions of the tubular epithelium remaining present the picture of necrosis due to the presence of a large number of strentococci and a fe v bacalli within the lumen Between these remnants of tubules is extensive inhitration with polymorphonuclear leucocytes fragments of r nalepithellum and some free blood. The bacteria found in the whole area of necrosis just described are chiefly situated in the remnants of tubules with a few scattered bacteria amon, the blood and puscells between the tubules. In the anemi area at the tip of the pyramid just described the blood vessels are entirely empty. There is no infiltration of the interstitual tissue. The tubules o t in I rge plugs of streptococci and bacill the former gre tly

predominate. In the small locenge-shaped areas in the repon of the straight trabules previously described the central area, that is the loamen of the turbule, is seen to consist of large numbers of strepto-cocci and a few bacilli. Surrounding this group of bacteria is the seen necrotic turbular epithelium surrounded by a zone of pos-cella. Among the pracells of the periphery hacteria are found with great difficulty. The pelvis of the kidney contains streptococci and bacilli.

Case 3 Assisper No. 3575. West Surgical Sorgios Male, age 22 March 26, 105 Assisting Assistance 27, 105 Assisting Assistance 27, 105 Assisting Assistance 27, 105 Assisting Assistance 27, 105 Assistance 2

Assessy 181 hours post mortem. Anat micel diagnosis Operation wound curbuncle of neck, esbecases of lungs, myocardium, kidneys, and rectus muscle, small mural throubles right ventricle, acute pericarditis, peritonitia, soft spicen, staphy

lococcus septicarmia.

All one Combined weight 300 grams. Capsules sturp saily. Surfaces show as averal points minut yellow the prost altrasted singly and in groups. On colon those are seen to be the surfaces of small colored are seen to be the surfaces of small overtex but in many instances they extend d wn often which the central portion of a pyramid as f as the middle if the pyramid. Marking retained cortex not narrowed. The pelves, uretern, bladder and urethra are negative.

Microsc pic ex m natio There is orden a with some few areas of acute degeneration throughout the otherwise normal kidney these. Numerous sections show the presence of abscesses, mostly in the cortex (Figs. o, o, and) some in the pyramids and one or two at the tips of the pyramids (Fig. 1) In name of these is there evidence of embolism. majority of the abscesses of the cortex appear to take origin in glomerull. The abscess is surrounded by a generous polyn clear infiltration. I most in stances the abscess is situated few millimeters below the surface (Fig. 9) In these instances the tubules leading down into the kidney substance are seen filled with polymorphonucles leucocytes and surrounded by considerable polynuclear infiltra-tion of the interstitial thane (Fig. 1) These tubules often lead downward to a second and even third abscess apparently of more recent origin than the one near the surface (Fig 1) These secondary abscesses show the tubules both bove and below them t be filled with polymorpho clear leuco-cytes t a considerable distance from the bucess In one instance a third abscess was found located just beneath the mucosa of the pelvis in the tip of the pyramid and showing a fin line of interstitial pus-cell infiltration connecting it with the overlying

two abaceases (Fig. 1). A noteworthy observation found with constancy is that where an abaceas is situated a few millimeters below the surface of the kidney the tubules above, although they may be surrounded by pus-cell infinitation do not contain pas (Fig. 6). while those tubules below the abaceas contain considerable pass (Fig. 10).

Baderielegical peri Cultures from the heart blood, operation wound abscess of the rectus muscle and fluid from the peritoneal cavity show profuse

growth of stanhylococcus albus

Sections stated for betteris show only taphylococid. These are found in large masses within the shocases, are almost universally found within the tubules to taining pag, are occasionally found in apparently undamaged tubules immediately beneath abscesses, and are found in large pags apparently arrested within the t bules t the ups of the pyra mid. The pelvis contains considerable number of staphylococid.

2 THE LESIONS PRODUCED BY PROGENIC ORGANISMS DIFFER IN ESSENTIAL PAR TICULUS AND ARE DISTINGUISMABLE FROM THE SE PRODUCED BY NOV PYOGENIC ORGANISMS

In much of the literature of renal infections one must inevitably infer that the authors believe that no definite distinction can be drawn between lesions produced by different types of bacteria. Thus Mallory in his Principles of Pathologi al Histology p. 573 82378

The leasons produced by number of organisms may closely resemble ne another. On this account an et ological classification is ordinarily carried out with only a few granisms such as the tubercle bacillus of terponema pullidum.

Following the same idea he says somewhat later

Infections agmis which most commonly produce leaturn of the kilney are the staphylococcus arrest, the streptococcus progenes, the bacillus coll, and the tuberde bacil s. Other organisms which occur less commonly are micrococcus lanceolatus the bacillus m osus capsulatus, actinomyces, and treponera pullidum.

Thomson Walker has this to say upon the subject of the bacteriology of renal infections

The bacilt s coil communis is the most common cause of renal infection occurring in 7.5 per cent of cases. The next most frequent are the staphylococcus (especially the rem) the streptococcus, the proteon of H user and the bacillus procyaneus.

A little later under the heading it. Pvelitiof Premancy he say

The bacteriology is imilar to thit other rinal infections

In contradi unctinit these view we believe that the learn produced by the occa and progenic bacilli the progenic group differessentially from the learn produced by non-suppurative organism chiefly the colon typhoid group.

3 THE LETIONS PRODUCED BY THE PROGENIC

These lesion con it of perinephritic absects cap ular abite cap ular certical absect septic intarct and diffuse uppuration. In upport of the proposition we ubmit case a to be inclusive.

The patient however ontinued to loss ground and became progressively weak r. The temperature again rose. He developed phlebitis in right legsparticity in right han I and arm and swelling of left parotid region. Died on the thirty-eighth day

Intobsy hours post mortem Anatomical diagnosis Carcinoma pancreas and adjacent glan is involvem at of the liver and glands along the abdominal aorta and illuc vessels, abscess in tusue of the abdominal wall acute purulent phlebitis ordema lunes with abscesses of upper right lobe and lower left lobe, degeneration of the kidness with

subscute abscess formation.

Aidness enlarged Combined weight 544 grams Cortices 5 to millimeters Capsules strip with a few adhesions Surfaces yellowish red with thickly sown pinhea I to bean sized areas, yielding on section. whit semi fluid pus. These areas are more nu merous in the right Lidney. On section the pelvis is not remarkable The markings are indistinct in places. Scattered through the tissue are small vellowish areas and patches mostly in or near the cortex. In the left kidney but also showing every where in the right kidney are vellowish streaks extending down from the cortex into the pyramids The bladder shows nothing abnormal

Bute sological report. Cultures from the heart blood liver kidneys pleura spleen, and pus in the peritoneal cavity show staphylococcus pyogenes aureus. Pus from the peritoneal cavity shows in

addition bacillus coli communis.

Mi ros opic examination shows a few scattered darkly stained areas equally distributed through the cortex and pyramids. These areas are on the average the size of a pinhead. In the pyramids they seem elongated in the direction of the tubules On examination they are seen to consist of numerous pus-cells closely packed together in the midst of which remains of kidney structure are rather faintly indicated. Interspersed among the pus are small granulation tissue-cells. This condition would indicate that the process had lasted for some time These areas ar abscesses in the process of healing Considerable granular detritus and colorless ring like bodies lie in the lumen of the tubules. No emboli are made out

Sections stained for bacteria Right Lidney shows in one corner of the section several small abscesses

two or three times the size of a glomerulus, all of which seem to take origin from glomerull or the neighboring proximal convol ted tubules (Fig. 14) In the centers of these areas are large masses of In the centers of these areas are argo manner of staphylococci. There are many new connective-tissue cells. Surrounding the abscess areas there is a diffuse infiltration with new connective-tissue cells and polymuclear leucocytes. Ma v of the tubules leading toward the pelvis from these areas show plugs of pus and desquamated epithelial cells thickly studded with phagocyted bacteria. In the region of the distal convoluted tubules such bac terial plugs are seen to f rm the centers of mall abscesses. Throughout the remainder of the section the tissue is for the most part unchanged. In some areas, however there is considerable descuamation of the epithelium of the tubuli contort! In all such portions of the sections the blood vessels are seen to contain large numbers of staphylococci most of which are within the leucocytes (Fig. 14) In several areas the capillary entering the glomerulus and the tuft of the geomerulus contain large numhere of taphylococci (Fig. 15) In the glomeruli the staphylococci are seen lying in the capillaries and also free in the capsule of Bowman (Fig. 16) In none of these glomerull was there any extravasation of blood into the capsule indicating a rupture of the capillary In one of the glomeruli, in which a fortunate plane of section shows a considerable por tion of the first part of the tubule, bacteria are seen not only lying in the capsule of Bowman but enter-ing the tubule (Fig. 17). In all portions of the convoluted tubules considerable numbers of bacteria. are seen in the tubules but mostly contained within the vithelial cells (Figs. 18 and o) In the straight collecting tubules bacteria seem always t lie in the lumina of tubules. In the pelvis staphylococci and bacilli are found. The pelvic mucosa looks normal. Some few bacteria are to be found in the interstitial tissue, most of them lying in the lymph

NOTE.- This kidney soems to indicat that there has heen to general infections. In the first there was con sterable aboves formation resulting, which had begun to heal. There seems in addition to have been severe arpticemia, many bacteria from which are seen in the process of excretion through undamaged glomeruli.

CASE 13 Autopsy No 3 West Medical 510-161 Male age 60, September 10, 1808. Present illness. Has bee sick for two weeks with dyspects as chief complaint. Physical exami ation shows nothing of interest saye high temperature and abscess back or neck. White bleed count 82,000 Uri e add, doudy albumin, slight trace sediment few hysline casts, blood, leucocytes. Died fourth day Dircharge diagnosis. Septicemia. Abscess of neck.

Astropy 6 hours post mortem. Anatomical diagnosts Phlegmon right houlder multiple abscesses lungs, supporative nephritis with in farctions, acute hyperplasia spicen, decubitus.

Kidneys Cansules free cortex of normal width. markings retained Here and there in the pyramids and in the cortex are a few grey opaque pinhead sized points. In ne kidney there is large wedgeshaped area extending from the base of a pyramid upward to the capsule. The tissu is paque pale, and the outline is marked by a grey some Pelves ureters, and bladder normal

Hiere sic examination. Micrococci seen in the becauses. In one or two instances plugs of micrococci are found in the small vessels. Cultures from the carbuncle in the back abow stanhylococcus pyorenes aureus. Heart blood spleen, liver and

kidney the same.

Sections staned for bacteria. One area the mail nyramidal area i suppuration poprently takes onein from bacterial embolus in a small artery In other instances the gl merull are clearly the seat of abacess formation, while in still others plum of hacteria are found in the 1 mins of tubules surrounding which there is narrow area of necroals of epithelium, outside of which is infiltration with polyn clear leucocytes. I still other areas staphy lococci singly or in small groups are found in the arterioles entering glomerull. I the glomeruli they are found within the capillaries and in the tubules. in many cases phagocyted within epithelial cells of the convoluted porti. In som instances bacteria are seen within epithelial cells in pparently normal t bules.

CASE 4. Autopsy ... Male, age 65 May 507 West Medical 76 47 Male, age 65 May 9 0 Present illness Eleven months painful and difficult uring a o Present tion brown, cloudy urine Four months severe gastric sympt ms suggestive of cancer Tambers tere normal t entrance. Lrine alkaline, albumin alight trace, occasional cast. No urine culture recorded

Four days later without apparent reason nations began t ha e hematuria with small amount of pus, accompanied by rise of temperature to and died the third day following.

Intobry 8 hours post mortem. Anatomical dlagnosis. Adenocarcinoma stomach, multiple cardnoma of small intestines, chronic nephritis, suppurative nephritis of right Lidney renal and ureteral dilatation, arteriosclerosis. cholelithiasis, small fibroma of bladder wall.

Kidasys Combined weight 200 grams. Left kidney capsule strips but is somewhat adherent. Cortex is to millimeters in width. Left ureter is slightly dilated along its entire course but opens freely into the bladder. The mucosa is negative. Right kidney capsule strips with some fine adhesions The granular surface is dotted over in many places with min te yellow spots. On section the tissue is firm, corter estremely narrowed. The yellow spots described as present on the surface project down for the kidney tissue as minute, small, reddish irregular areas. The pelvis is slightly dillated. The m cost is smooth. The right ureter is dilated its mucosa is amooth and opens

luted tubules show hyaline degeneration (Fig. 23) In a few of these the epithelium is desquamated and is found in the lumen of the tubules lower lown The lumina of the tubules are generally filated particularly in the pyramids in whi h area there is also onsiderable interstitual thick ning. The mucosa of the pelvis is much thickened and infiltrated with pus-cells (Fig. 24). Just beneath the pelvimucosa is infiltration with round cells and a few polynuclear leucocytes extending into the pyrami ls for a distance of centimeter. Sections of the ureter wall show some infiltration of the muscularis with some areas of polynuclear cells in the periure teral tissue. The mucous membrane is much thick ened and infiltrated with pus-cells. The submucosa shows d nee lymphocytic intiltration (Fig. 25) with a few pus cells

Sections stained for bettern show no bactern throughout the greater portion of the kidney. The area of submu osa infiltration in the pelvis tips of pyramids and the ureter show a few scattered bacilli. The pelvic and ureteral mucosa and masses of debris within the pelvis and ureter show large numbers of colon bacilli. The groups of dequamated epithelial and pus-cells previously distribed in the lumina of the convoluted tubul's show no bacilli. In some few areas single bacilli were found in the lymphati's of the interstitual tissue of the pyrami!

Opera-C mplet hysterect my with drainage Patient extremely poor condition from shock at the end i operation. After operation patient continued t run a swinging temperature rarying from 8º Developed tenderness in both costovert bral angles. Gradually failed and died on fourteenth day. I no specimen reported on day of death was said to have shown no all min sediment was t done Autopsy 201≤ hours post mortem. Anatomical diagnosis Hysterectomy circum scribed pentonitis with purulent infiltration and necrosis of tissues of the abdominal wall near wound, multiple old infarcts of spleen, chronic mitral endocarditis, bolehthiasis, suppurative nephritis.

Addres capsules strip easily and leave granular strates thickly dotted over is increased in width 8: 9 millimeters Corticas present a mottled gray opaque poperance from the presence of numerous discrete and confinent pinhead sized opaque areas. Pyramids show gray lines. The mucosa of the pelvis hows ridl rung and e hy motic areas. Bladder redden i

Buteriel is alr p rt. Cultures from heart hy r spleen and kidneys show colonies of a basillu which was not classified but seemed from it growth on agar to belong to the olon group.

Mi ros opi naminate of the history how some post mortem degeneration extrained inhibitation it polynuclear leuroxytes with disarpointane it the renal epith hum over con ilerable area of the use of that absentes are formed some lilat i tubules filled with polynuclear liu oxyt and epith halfells (fig. 20)

Sections stained to had rid. The pitur is typical of a pyel nephriti. Fig. o. (1 m ruli are as a rule free from halt ma ind also free from pus save where invaled from neighboring tubule proces es. The inter titual ti sur hows on i lerable lymphocyte and some pus ell intiltration. Through out the se ti n the tubule are dilated an i filled with clumps of bacteria pu and 1-quaminated epithelium. Lew ba ter a are found out ide the Wher bacteria are found out if the luming of tubules, the renal epithelium i u ually extensively destroyed with civil n > 1 liberation of the contained bacteria (Fig. 30). Wher dennite abscess formati n'appear close observati n'honthe centers of apparation to be r mnants. It all ales which have been extent ly destroyed appearan e of true aboves is fue to influin e of the destructive processes in everal neighboring tubules. There are no coca seen in the section Large number of gram negati e bacilli mostly in tubules are clearly the etiological factor in the DTOC 6-5

Note: The straking similarity between the find ogs in this are and the precing (2.4.2) is of interest because in the former the conditions (f) as ending intertion in its while in this label to the strainmarks in can the bladder be mad red the rigin of the renal condition. One might be an ascending intertion to their clear sannot be set the pathological pictures presented are in distinguishable.

In this group of cases acute pichtis and also chronic pichtis are shown in Cases 20 30 31 32 and 33. Acute piclorephritis does not appear and its incidence is interential as we shall later show. Chronic piclorephritis is shown in Case 30 as is pionephrosis.

INFECTION OF THE KIDNEY WITH BOTH ON PROBENIC AND PROPOSED ORGANISMS WILL PRODUCE A MINTER OF THE LESIONS CHURACTERISTIC OF BOTH GROUPS

This fact we believe explains the not un common tallact that the colon bacillus will produce abscess of the kidner. This has been freely tated and appears to have been upported by the evidence of cultures ob-

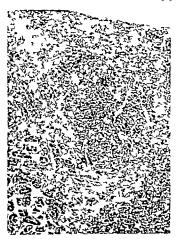

Fig. 3. M resplictograph fittue but due to bacilli.

One if the organisms is the lo bacillu the ther a gram posture organism. Photo b. L. Brown x o.

tained from the Lidney. This reasoning we have shown to be tallactous for two reasons Fir t cultures containing both colon bacilli and cocci will frequently be interpreted as showing only colon bacilli since this organism grows with great rapidity and readily obscures the colonies of cocci Second at has been a sumed that the cultures obtained from one part of a kidney represented the lesions produced in the whole kidney This we have shown to be tallacious by the actual demonstration of bacille in one portion of the kidney cocci in another and cocci and bacilli associated together in still other portions (Fig. 31 Our experience has led u to believe that in these mixed infections the colon bacillus probably precedes the coccus in point of time. Only in this way can be explained the appearances in certain kidneys which will be below described. These mixed lesions are rather likely to be found in cases occurring in Group II of our cla sincation

that is to say kidneys handleapped by prenous disease. In support of these propositions we submit Cases 34 to 56 showing mixed infection with cocci and bacilli Cases 67 and 68 showing infection with two different kinds of cocca, and Cases 59 and 60 showing infection with two different kinds of bacilli

Kidneys Capsules strip leaving smooth surface On section tissue mottled red and yellow. In ne pol of the left kidney chestnut sized red y t Scattered throughout tissue many peasured attestives are some of three abscesses forminue as darited areas down into the pyramids. The papillary porti no of the pyramids shows yellowish whit streaks. Cultures from Lidneys show a staphylococ cuts aureus and colon bacilli. Sections its ned factoria. No abscesses in sections preserved Gram negative bac lil clumps of staphylococci and some bacilli are found in the convoluted cubules.

CASE 46 Autops No 1164 South Surgi cal 87-55 Male age 63 November 5 1903 Present illness Eight years ago abacess of perineum, now has fillform atricture. Urns at entrance acid, trace of albumin sediment dumps of pas, occasional red blood-cell. Patient ran an irregular temperature and died, after operation on the seventy-third day Clinical discreption.

Assistor Anatomical diagnosis Pronephrosis, cysitis, chronic urethritis, perineal fistula, dilatation of urriers and orterfitis, bucess of left kidney chronic interstitial nephritis, abacess of left epididi mis and testi

Kidneys Somewhat smaller than normal capsule adherent. Pelvis, caliers and ureters on the right are markedly dilated and filled with a thick yellow pus. The course of the right areter is tor tuous and at its lower extremity at the bladder wall forms somewhat of a cul-de-sac. The right pelvis is blackish in color and granular The walls of the pelvis and ureter are thickened. The pyra mids of the right kidney are flattened and the co tex narrowed. The markings are becured. Th left renal pelvis, calices and ureter are also dilated. They do not yield pus. At two or three places there are cavities in the substance of the Lidney filled with pus. The walls of the kidney pelvis and ureter are thickened. The bladder mucosa as dirty blackish in color and rough.

Microscopic eresti ation. A section from on kidney shows fibroid strophy of portions of the renal tissue and an abscers.

Pastrilabelial report Cultures from the heart blood show a few atreptococcl. Sections stained for becteria show staphylococci and gram-negative bacilli scattered throughout the kidney sections. It is impossible to differentiate the extent of post mortem invasion.

CASE 41 Surgical Case N 9 34. South Surgical Programs are 43 November age 43 November agriculture and the surgical Post kistory negative save for symptom attributed t the appendix Persent illustra to one week patient has had abdominal pain localizing in the right loin with chills and fever T negetature at entrance 100 with blood count 5,100 Links ackl, small trace of albumin, considerable puss.

Rectal examination shows tenderness high up in the rectum with orderns and fluctuating mass. Operation i cision and drainage of ischnorectal absects. Scenal peration appendentomy and nephrot only with drainage of hermatogenous kidney

Specimen excised for examination.

Pathological report Tn small pieces removed from surface of the kidney red, hemorrhagic with red cells and some leucocytes. Section staused for hosteria shows staphylococcus and large grammary.

iositive bedlins in sistenses. CASE 48 Autorps No r635 South Surpcal r60-85, Male pc 64. September 3 9 a Para kittery Frequent catheterisatio for past ten years on ecount of bladder inflammation. Present illuses. Complaint frequency Urina acid, trace of albumin, leucocytes and many batteria. Operation Emploratory Inparedomy for

tumor of the bladder Bladder palpated but not opened. Operation wound remained clean. After operation patient failed without apparent cause and died thirteenth day Cli leaf diagnosis Multiple directicula colarged prostat cardiac insufficience.

Autopsy 8 hours post mortem. Anatomical diagnosis Suppurative nephritis, acut pyclitis, arterioscieroti degeneration of kidneys, hypertrophy of prostate, hypertrophy of bladder wall

with diverticula, operation wound.

Kilaryr Combined weight 10 grams. Capnules attip leaving granular surfaces the tisse is
quit firm. The cortex measures 10 6 millimeters.
Here and there the section surf cas are streaked
and mottled with small yellow areas. The pelves
and calcers are moderately disted. The mucosa
is greerally reddened. The walls of the Isadder
are thickened. A few diverticula and one large
one are present. The postate is considerably
cultured.

Hiere capic argumentum. There is extensive infiltration with polynuclear leucocytes, in one or two places absent f rmation.

Bacterial gual report. Cultures from the heart blood show growth.

Sections ato see for bacteri Sections from the kidney thatee which were preserved show but httle suppurative process Staphylococci and bacilli are found, few in number in the pelvis.

CARE 49 Autopsy N 31 South Surgical 3-4. Make 76 66 A great 1899. Present if as Prostaile 31 implicing nevern years. Catheterized one in the ago and apparently in fected at that time. Of ed. 8 Prostatectomy trues smoky acid, large amou to figure some blood large trace of albumin. Died emby-girth day Clusteal diagnams. Hypertrophy of prostate, pneumonam.

Astepsy bours post mortem. Anatomical disposas Suprapuble cystotomy and partial prostatectomy bacess of region of Scarpa's triangle with sanus formation, thrombosis right femoral ven, abacess of lungs, acute pyellits with abacesses of

kidney ulcerative prostatitis

Kal ys In both renal peters marked indumtion of mucons with som patches of crudate. Cortex 5 millimeters. Tassue slightly pole and in some of the pyramids greyish yellow streaks in the papilla. I one kilney there are two or three pinhend sized abscesses. Sections of the small abscess of th kilney sh w micrococc with cloudy welling of the epithelium of the cortical tabules.

Section statued for bacteria show staphylococci in abacesses, bacalli in the yellowish streaks in the papella lying within the tubules, bacilli and cocci

in the pel es.

Cast 50. Autoray No. 2030. West Medical Son- 5 Female age 47 October 6 971
Present illness Two years of abdominal symptoms, one week of diarrhora followed by distention of the abdomen and bodominal pain with much yomitine

Temperature at admission normal Later a some what irregular fever reaching 100 Urine at admission no albumin, rare leucocytes. White blood count 8500 Clinical diagnosis. Cancer of the stomach disseminated abdominal cancer.

iutopry 28 y hours post mortem. Anatomical diagnosis. Diffuse carcinoma of the stomach with extensive metastasis including the right kidney carcinomatous strictures of the large intestine left bronchopneumonia chronic endocarditis of the nutral valve with stenosis suppurative nephntis hydronephrosis right due to constriction of the ure ter by neonlawn small infarct of lune.

Kidneys Combined weight 26.1 grams right kidney is small. There is much perinephnic induration and thickening marked about the ureter especially in its upper portion. The pelvis and call es of the right kidney are dilated and ontain a cloudy fluid. The surface of the right ki lnev is fairly smooth with a few ill-d fined gray white areas both discreet and confluent. On section these areas ext nd for a variable distance into the renal tis u beneath. The markings of the cut surfaces are obscured The renal ortex is narrowed The ortex of the left kidney shows numerous small abscesses. The tissue about these in many in tances is dark red. These areas are se n to extend into the ortical ubstan e in the form of vellowish gray treaks. The protect is not fillated. The l lad ler is negative

Mirs opi examin tion. One section from the right kidney shows an area of car moma. There ar numerous areas of suppurative n phritis.

Bacteriological report. Cultures from the heart

blood show scum of growth. I several types of bacilli-Sections stand for botters. Abscesses show only occr some gram or gative bacilli are found in the lymphatics and the blood stream. In the pyramidal portion of the kildney, large plugs of bacteria both core; and bacilli are found in the tubiles.

CASE 51 Autopsy No 1352 Genito urinary 10-155 Male age 28 April 25 1914 Past history Stricture of urethra for five years in ternal urethrotomy three years ago Pres nt ill ness. For one year has had recurrent pains in right kidney without fever. For two weeks has had in reased frequency followed by severe pain in remon of right Lidney and vomiting His urine has been much more cloudy than previously. Lenne acid, loudy large amount of albumin much pus and a few red blood-cells. Il lute blood count 10 000 (vstoscopy showed cloudy urine from the right side with markedly decreased function left kidney mod erate amount of pus 10 per cent function. Cultures from both kidney urines showed colon like bacillus, 1-ray showed right renal calculus. Operation Right kidney full of small calcult removed by pyelot omy and nephrotomy Luft kidney showed pen nephric abscess with many miliary abscesses in cortex Patient died fourteenth day Clinical di agnosis Calculus pyelonephritis right acute suppurative nephritis left uramia and pneumonia.

Autopsy 13.4, hours post mortem. Anatomical diagnosis. Nephrothikiasis, diphtheretic pyeltus and pyonephrosis pennephritis with abscess formation chronic interstutial nephritis right with chronic urcteritis double nephrotomy with purilent in ilitation of perinephric tissue tuberculosis of the lungs bronchopneumonia, focal necrosis of the bladder absence of left testicle scar of old cystotomy fatty liver strentococcus septicemia.

Aidneys Combin d weight 330 grams Abacesa of pennephric tissue about each kidney Right kidney shows adherent capsule. Surface is marked with occasional irregular depressions. In the substance of the kidney extending from the convexity to the pelvis is an irregular exervation bounded by ragged ne rotic kidney tissue bathed in pus (Nephrotomy wound) The pclvis is moderately dilated its mucosa covered with a dirty white layer All the call es are dilated and contain irregular grapular concretions and pus. The cortex is mark edly parrowed. The left areter is adherent to the urrounling tissu. Its mu osa is smooth right Lidney has an adher nt capsule on removal of which several cavities filled with yellow pus are exposed. There are numerous pinhead sized abscesses on the surfa c In the substanc of the kidney ex tending into the pelvis is an irregular ravity bounded by necrotic tissue (Nephrotomy wound.) The renal pelvis is moderately dilated and filled with nus two concretions. The mucosa of the pelvis shows an adherent dirty layer The left ureter is not remark The bladder and prostate are normal

Micros opic examination. One section of the kidneys shows suppurative nephritis, another section shows strophy and a round cell infiltration. At the tip of the pyramids in one section is necrosls and purulent infiltration.

Bacteriolerical report. Cultures from the heart blood show profuse growth of colon like bacilli and cocci. Sections stained for bacters. In the section preserved there were no abscesses and small evidence of suppuration. Many staphylococci and a few gram negative bacilli were found in the pelvis.

CASE 32 Surgical Case No 8127 East Surg cal 506-207 Female ago 25 January o 1908 Past history Painful meturition since childhood. Present illness Four days of right-sided abdominal pain with vomiting later pain localized in right lidney region, unite became cloudy Line at admission alkaline slight trace of albumin, much pus Temperature 103 White blood-cell count 15 600 Physical examination showed a mass similar to appendix abscess and thought to be that Operation Exploratory Japarotomy and nephrec tomy for acute Infected kidney Uneventful recovery Cultu es peritonal fluid, no growth, pus from kidney abscess shows few cocci and bacillic Clinical diagnosis Acute infected kidney.

Pathological report Kidney very much enlarged On the surface multiple small purulent foci on section the same are seen n the cortex of the kid

ney more rarely in the papilla.

Microscopic examination Infiltration with round and pus-cells and destruction of the tubules espe-

cially in small foci.

Sections stained for bacteria. No true cortical abscesses found in lisme. The picture is more that of a colon bacillus preioneophritis with tubules the center of suppuration. Bacteria found in these areas show mixed infection of staphylococci and gram-negative bacilli, the latter predominating.

Cast 33. Sengical Case No 710-17 South South Sengial, 5 if Female, ag 3.4 Cobbe 9, 1007 Present illustra Eight days ago onset of adominal pain in region of appendix with fever which quickly subsided los ving socroess in region of kinner Physical crossinations. Right kidney palpable and tender X-ray negative Urnas tentrane acid, alight trace of albumin, some pus. White court 1,300. Guinea-pig inoculation negative for thereinous 50 Postilos, Nephrectomy Kidney slightly enlarged, pake, few areas of discontion. It was thought to be the cause of the trouble and removed. Clinical diagnosts. Colimeton prediocognitis. Recovery

Pathelegical report Enlarged soft kidney with opeque yellow stripes and dots in the pyramids sur

rounded by reddened zones.

Hieroscopic examination Foel of round-cell infiltration in many places with intense congestion of surrounding versets. Epithelium of the tubules swollen, desquamated and the lumen filled with hyaline and granular casts. Column from the kid new tissue at operation, colom bacillus.

Sections storaged for locateria. Considerable number of gram-negative bacilii in the tubules and peives with a typical picture of colon pyrionephritis. Here and there in the cortical region are small abscesses with a mixed infection of gram-negative bacilli and large numbers of staphylococci.

Norz. - A colon pyclonephritis with superimposed

staphylococcus abscess.

CARE 54. Autopsy No. 2 64. West Surgical, 505-56; Female, age 54. May 28, 1908 Pair Shistery Marked coostipation for four months, Presset illness: For five days acute abdominal left-sided pain with chills and fever temperature of

101-104 with pusy urine.

Two days ago acute tender red mass appeared in the left kidney region. Uriss acid, very slight trace of albumin, small amount of pus, microscope blood. White blood crass, 25,000. Culture from the urine aboves colon-line bacilli. Operation nephrotomy for spekt kidney. Kidney considerably and symmetricity cultured, set and pulpy with scattered small absences of the cortex. Pelvis nor distance, the contract of the cortex. Pelvis nor fourth day after operation. Cli lesi disposition fourth day after operation.

Astelly 714 hours post-mortem. Anatomical diagnosis Carcinoma of vagina with obstruction and dilatation of left ureter left ureterits, pyelitis and suppurative nephritis, nephrotomy wound.

streptococcus septicamia.

Ked ees Right Lidney weighs 171 grams. Canapiles, trip with some difficulty, leaving a granular surface. Cortex measures 6 millimeters. Markings are fairly distinct. There are no abscesses in the right kidney Right ureter is n t remark able. Left kidney weighs 208 grams perinephric fat asparated from the kidney and the space is filled with bloody purulent material. On the con vexity of the kidney there is an irregular opening 6 centimeters in length leading into the polyls. The walls of this cavity are composed of soft necrotic kidney traspe. At various places in the cortex and extending int the pyramid the kidney timue is transformed into soft yell wish black, semi-fluid mat These areas to wedge-shaped with free pus at the surface. Generally they are sharply outlined from the surrounding renal tissue. The surface of the cortex where not involved in the bove-mentioned necroti area bout the wound shows indistinct markings. There are no abscesses of the kidney The mucosa of the pelvis and ureter are reddened and the lumen contains purulent areas. The lower half of the ureter is dilated and its lower end is pressed pon by tumor mass.

Murescopical examinatio hows acut degenera

tive change with suppuration.

Bacteriological report Cultures of the heart blood and spleen show streptococcus and colon like bacillus.

Sections stained for better! There are chalms of streptococci in small arteries and in the capillaries of the glomerul! There are few dumps of streptococci and gram-negative bacilli in the straight cot letting tubules. There are also a few bacilli in

the blood stream.

CARY 55, Autorsy No. 250 West Medical, 370-6 Male, ago 5 May 18 90 or Present Unexis.

Six months weakness, some names, occasional voniding restlessoess t night, loss of appetite, nocturia three or four times, atght irequency. Has a labtory of hematura once within that period. Physical consistence of cortex and under side of both thights and orderess of outer and under side of both thights and with the contract of the contr

Assispy 19% four post mortem. Kidneys Combined weight 365 grams Сарsules easily removed revealing small abscesses on the surfaces of both kidneys. In places these abaccesses extend a distance into the cortex and in a few instances as streaks as far as the tips of the The Lidneys are not dilated ureters pyramids The bladder presents an ecchymotic gray are free red mucosa. The prostate shows an abscess 3 centimeters in diameter of the right lobe

Microscopic examination Sections of the kidney

show abscesses

Bacteriological report Cultures from the heart liver and spleen show staphylococci and streptococca. Cover glass preparations from the pus in the wound show streptococci Sections stained for bacteria Abscesses in the kidney tissue show dumps of streptococca and staphylococca. In one abscess there are two large masses of bacteria one of which seems entirely a streptococcus infection the other entirely a staphylococcus infection

CASE 58 Autopsy to 1731 West Medical Female age 32 June 30 1906 Past 644 161 history Four years ago post-puerperal sepais Present illness One week ago began to have re current attacks of chills without other symptoms Patient came to hospital in prostrated condition high temperature pulse and respiration. Lrine very alight trace of albumin moderate number of red blood and pus-cells. If hite count 13 000. Pa tient continued to grow worse and died fourth day Clinical diagnosis Septicremia origin unknown,

Autopsy 19 hours post mortem Anatomical diagnosis Malignant endocarditis of mitral valve bronchopneumonia, purpura hemorrhagica in farcts of spicen and kidneys suppurative nephritis septicemia staphylococcus pyogenous aureus early pregnancy and abortion

Kidneys Combined weight 320 grams. The capsules strip easily leaving a dark reddish surface dotted over with minute yellow points, dark red spots and here and there small irregular confluent abscesses The small yellow areas mentioned are seen to be the outer surface of fairly hrm homogeneous masses surrounded by blackish red kidn 5 tissue from which they are sharply ma ked off. In

some places these infarcts are situated in the cortex. while in others a few extend from the bases f pyra mids to the cortex. In the pyramids are to be found numerous vellow streaks and spots. The cortex measures to 6 millimeters. The m case of the pelvis shows minute blackish red spots. Ureters and bladder normal save f few ecchymotic areas. Microscopic examination The kidneys show

necross with abscesses and hæmorrhage.

Bacteriological r port. Cultures from the heart blood and spleen show pure growth of staphylococ ous processes aureus. Sections stained for bacteria show in the discreet abscesses mixed injection of strentococci and staphylococci. In many places the vessels are found plugged with bacteria most of which are strentocood, although all were found to contain considerable numbers of staphylococci

CARE 50. Autopey No. 108 South S recal 70-97 Female, age () June 26 903 P escat high fever finally localizing in the rall-bladder region. Uring neutral reaction trace of albumin occasional blood and pus-cells, no casts. White Head count 80,000 temperature varied from 00 to 04 Patient was not operated on and died of sepals on seventh day Claucal diagnosis Chole-

lithlasis, cholecystitis, suppurative ephritis 4 stepsy 414 hours post m riem. Anatomical diagnosis Pyonephrosis, pyelonephritis chole

Ilthiasis, icterus, fibromyoma of the uterus. Kidney Left Lidney is apparently normal right kidney is enlarged, and its capsules strip leav ing smooth surface dotted here and there with minut yellowish abscesses. On section the tissue is soft and section surface show numerous mi t nurulent areas. The cortex is of good width the pelvis is dilated and contains yellowish brown, foul.

purulent material. Ureters and bladder show noth ing remarkable. Hierescopic ex mination Sections of the kid

ney show the usual appearance of pyclonephritis. Sections of the left kidney show only ordems.

Bacteriological report. Cultures from liver and

spleen show scum of growth of bacilli. Sections storaged for bacteria show considerable numbers of gram-negative colon-lik bacilli in the arteries and in some of the tubules while a consider abl number of a smaller gram-positive bacillus are to be found in abscess areas.

CARE 60. Autopsy N #85. East Surgical, 318-6. Male, ago 80, June 14, 808. Present illness Patient admitted for retention. Could give o information about himself Temperature 100 vomiting, died soon after entrance. Cl sucal

enesis. Enlarged prostate.

Autopsy o hours post-mortem. Anatomical diagnosis Adenoma prostate, diverticulum hlad der alight dilatation ureters, suppurative nephritis arterlosclerosis, senile emphysema lungs, papillary adenoma Lidneys. Kidneys Capsules somewhat dherent. Cortex

of each kidney somewhat narrowed. Kidney timue

pale opaque and soft. A few small abscesses beneath the cortex (Fig. 32) Cultures of the beart blood abow no growth. Cultures from the kidney abow several varieties of cocci and bacilli which are not differentiated.

Uscrescopic examination Kidney shows in the cortex extensive areas of infiltration of leucocytes with some disintegration of the renal epithelium. Glomeruli are not remarkable. Arteriosclerosis of the vessels, some areas of fibroid at only and round cell infiltration

Sections stained for bacteria. The predominating organisms in the bacers cavities are two types of bacilli one gram negative bacillus probably bacillus coli, the other long barred gram positive hacillus

ha ill dearly seem the etiological Norr — There t f ctors in the production of amouration although occasonally cocu are found. This case shows considerable post mortem in asson high may explain the presence of the variet, of regardance found yet the occurrence of the tw bacilli described abov in large numbers and confined to alwoom cavities seems t indicat that they are the etiological factors

THE LESIONS OF 80 CALLED ASCENDING IN FECTION ARE HISTOLOGICALLY INDIS-TINGUISHABLE FROM THE EXCRETORY TYPE OF LESION

It has been customary to assume that there was a definite lesion produced in the kidney by ascending infection. This is referred to again and again in the literature and is often spoken of as the typical lesion of ascending That this distinction cannot be Infection maintained appears to us to be conclusively shown by the two following cases (32 and 33) Without reproducing here the whole evidence printed above we may note that Case 12 was that of a man whose unne was normal at the time of entrance to the hospital. Following operation for cancer of the atomach, retention of urine took place and he was catheterized regularly until the day of his death three weeks later During the process of cathe terization pus appeared in the urine and the case is typical of those generally credited with being ascending infection Case 33 was that of a woman interestingly enough of exactly the same age who died two weeks after an operation for fibroma of the uterus followed by injection of the wound. This patient had no urinary infection at the time of entrance was not catheterized during her stay in the hospital and at autopsy showed a normal bladder Nevertheless the lemons of the kidneys in these two case are inditinguily able as a glance at the illustrating figures will show. These cases are typical of several occurring in our experience and we think they are sufficient to require an abindonment of the belief that there is involved in the kidney typical of excending indection.

THE BEARING OF THE ABOVE OB LEVATIONS
UPON THE DIAGNO IS OF RENAL INFECTION

If we have increeded in establi hing the fact that the pyogenic organism produce lesions of the kidney esentially different from these or luced by non-py-genic or gani ms it follow that the fact has in important bearing upon diagnosifirst place it has we think been abundantly demon trate l by the f timony of many observers that organism concerned in renal infection appear promptly in the unine though they may not long continue to so ap That organi ms not concerned in renal intections may also appear in the urine is to be remembered. The evidence above referred to of the appearance of tubercle bacilli and lepra bacilli after the administra tion of salvirsan, the recent ob ervations of William H. Smith in regard to the appearance of organisms in the urine of patients with tever probably caused by a septicemia and a mass of extremely careful evidence all bear upon the point

On the other hand with clinical evidence suggesting a renal injection, the diagnostic importance of a careful examination of the urine can hardly be overestimated the lesions characteristic of pyogenic organ isms will show the bacteria in the unne perhaps only during the early stages. Since however these lesions are comparatively shut off from the lower portions of the kidney and as they do not involve the pelvic mucous mem brane pus in any considerable amount will be found rarely if at all By the same token since the lesions of the nonpyogenic group are produced chiefly in the renal pelvis evi dence of this fact is abundantly clear in the urine by the early production of pus accompanying the appearance of the microarganisms

A very striking difference is also to be ob-

served in the effect on kidney function as measured by phthalein of these two types of infection. Since the uppurative infections involve chiefly the criticy and computative little the convoluted tubules they would be espected to produce comparatively little effect upon kidney function thus measured and uch i in factions of acute renal infections with the cellor bacillus group is not typon the

nvoluted tubule the pelvic lesion though appearing early being we think secondary t the tubular lesi n Thi hould and in ta t die prieduce udden and protound changes in killney function the case decribed en p 408 being but one et a cen iderable senes of observation which we have previou ly discused in a paper on nephriti. 1 Briefly and somewhat dogmat ically tated theretore the diagnostic evidence a as tollow. It with clinial exidence uggesting a renal intection treshly drawn unne tudied a uggested by Crabtree shows cocci in abundance with a small amount of albumin a tew red blood corpu cles and many leucocytes or a little pus together with a renal function at or near normal limit diagnosis of coccus intection of the kidney is in tined. It on the other hand a similar examination hows many bacilli a little albumin and much pus coupled with a mark edly diminished kidney function a diagnosis of colon bacillus infection of the kidney is unavoidable

Though it is foreign to the title of this paper it may not be improper to suggest the bearing of these observations upon treat Clearly the suppurative lesions conment cern those portions of the kidney which are relatively inaccessible to drug and if these lesions are such as to require treatment, that treatment must be operative. On the other hand the lesions produced by the colon bacil lus group concern those portions of the Lid ney relatively accessible to formaldehyde containing drug and the surgeon is therefore justified in persisting in treatment by this method on the a sumption that if it be properly planned and efficiently carried out

Boston M & S J o 6 June Surv. Gymec & Obs 6 via. it will succeed in controlling the infection. This statement must not be assumed to mean that we believe that the formaldehyde containing drugs act upon the cells of the convoluted tubules. This we have no reason to assert, but the lesion of this portion of the kidney is a very translent one and such damage as is done by the acute process is rapidly overcome by the restorative action of the cells themselves. This particular lesion does not require treatment. It is the lexion of the pelvis and to some extent of the lower urinary tract that is the persistent and dangerous legion, and this can be reached by formaldehyde.

NOTE.- W wish t express appreciation of the valued services of Dr James Homer Wright director of the labora tory for lively interest in the work and for aid in collect ing material. Whave appreciated the privilege of appealing to his judgment on difficult questions arising during the progress of the ork.

Dr Oscar Richardson has kindly supplied from the

or open much valuable staterial.

Dr William H Smith has offered many beloful suggestions on the statuing of bacteria in tissue. Whatever of unusual merit our microphotographs may

show is due to the painstaking thorough ork of M L.S. Brown.

THE BASTEDO SIGN IN CHRONIC APPENDICITIS

B JACOB ROSENBLOOM M D PH D PHIBBURGH

In 1911 Bastedo (1) described a new test for chronic appendicuts. It consists in passing a colon tube eleven to twelve inches into the rectum and injecting air by means of an atomizer builb. He found that as the colon distends, paln and tenderness to finger poant pressure becomes apparent at McBurney's point, if appendicits is present. Dreyer (2) Rost (3) Slawinski (4) Hertz (5) Goodman and Lucders (6) and Bischoff (7) have described their experiences with this test.

Bastedo Hertz Drever and Bischoff consider colonic inflation of great value as a diagnostic sign of chronic appendicitis. Rost, however claims that Bastedo's sign is positive not only with diseases of the appendix but also in pathologic conditions in the colon. Rost also says that the pain appears only if there are changes in the mesenteriolum which brings the appendix into a certain abnormal relation to the cecum however Bischoff on the contrary has found the test positive when the mesenteriolum was entirely normal and the appendix alone was diseased. In the cases, that he examined after operation, there was no longer the slightest pain in the appendix re mon when the colon was distended.

Goodman and Lueders however claim that there us no constancy in the results of tained with this test, and it is in no some pathognomic of chronic appendicitis. They have seen no positive reactions in normal individuals.

I have personally been using this test, ever since its description by Bastedo and have found it of great service in the diagnosis of chronic appendicitis as may be readily noted by the accompanying tabulation of cases studied

I am convinced that this sign is of great value in the diagnosi of chronic appendicitis

RLIERENCES

SOME OBSERVATIONS CONCERNING POST-OPERATIVE COMPLICATION OF THE LANE SHORT CIRCUIT AND COLECTOMY

BY REA SMITH M.D. LOS IN LEES CHIEB IN

THE intestinal work of Sir Arbuthnot Lane, has been widely criticized in thi country with varying degrees of justice depending upon the knowledge of the writer or speaker upon the ubject and hi experience in dealing with these cases

If it be possible to summanze, the opinion of surgeons on the subject of relief of intertinal stasis by surgery. I would say that it can be expressed in this. There is no doubt that certain cases are greatly relieved of their symptoms of intoxication by one of the Land procedures but the result of the operation is too often spouled by complications which insection the surgery itself.

In this paper I shall take up separately the complications that seem to be peculiar to this particular type of surgery and attempt to point out the reasons for their occurrence and the logical way to avoid them

In ileocolostomy the one great fear of American surgeons has been the backing up of frees into the blind pouch of the cacum necessitating secondary colectomy. Lane 8 records in 1912 showed that this complication happened in 20 per cent of his own cases and that he was unable to forctell in which case it might be expected. A more careful consideration of the physiology of the colon will show that the remedy for this the greatest bugbear of the short circuit lies not in finding some method to prevent the ileal content from going back into the crecum but in assuring this content a free outlet after it has backed up The ileal content in all success tul short-circuit cases backs up into the blind pocket and the only ones that become impacted are those with a partially obstructed colon from which the solid residue cannot return

It has been repeatedly shown by the \ ray
that any fluid thrown into the terminal seg
ment of the large bowel will be curried im
mediately into the excum by reverse pen tal
tic waves. Here the fluid is absorbed and the

so-called normal peristaltic waves carry to more solid content back to the lower segme or container. This is precisely what happe after a short circuiting operation and the will be no difficulty with cacal impaction long as the colon is unobstructed. A simple hort circuiting operation in the obstructure, will not only be of no service but is defined to contraindicated. Either the obstruction must be relieved or the colon removed to the point of obstruction at the time anastomosis or in impacted occum we result.

To my mind the most seriou complicity

is that of unitual post-operative adhesis which by contraction cause obstruction varying from slight parrowing to comple cutting of the bowel Symptoms fro these adhesions are usually not apparent f several months after operation although lost one case from acute obstruction in t third week of an apparently smooth co valescence. These adhesions are peculiar that they are usually in patches and are t result of local pentonitis in widely separat parts of the abdomen These consta patches of peritoritis are due to direct info tion at the time of operation because of technical error in the arrangement of t steps of the Lane operation used almouniversally by American surgeons. In ma ing the anastomosis the infected thread whi sew through and through the colon wall handled by the surgeon touches the gau packs and renders the whole field unsten after which the patient is eviscerated and t split in the mesentery stitched. In spite the mo t scrupulous care on the part of t surgeon it is impossible to prevent some infr tion at the time and the handling of t whole abdominal contents in moving the small intesting to the upper abdomen accountable for the wide distribution of the As Lynch has uggested it is a east r urgical procedure to sen the mesente. before the anastomous is done and it is also safer to make the opening and sewing of the colon the last step in the operation, at which time the field must be considered infected, and the same care exercised to prevent the distribution of infection as is customary in operating in a recognized infected field.

The technique of intestinal anastomosis has been largely influenced by the development of the technique of gastro-enterostomy where it has reached its highest point of perfection This technique however efficient in the comparatively uninfected upper abdomen, cannot be used in anastomosis of the colon or terminal ileum, where the contents are highly infected. The wide application to all parts of the intestinal tract of this simple and effective method of sewing is responsible for the great preponderance of post-operative adhedons which are prope to follow all operations entailing the opening and sewing of the lower howel.

Experience has shown that late in the convalescence alarming symptoms develop in the cases in which a partial or complete colectomy accompanies the intestinal anastomosis. This occurred in my work until I properly appre ciated the importance of the physiology of the parts removed and adopted a very simple routine of supplying fluid to the patient before it became evident that it was necessary In six consecutive partial colectomies since that time I have not seen any untoward symptoms develop Lane gives a large quantity of saline solution under the skin while the Da tient is on the table and repeats it later if the nationt shows signs of needing fluid. Al though I followed Lane a rule, my early colectomy cases all became dehydrated, developed ramd pulse nausea, vomiting and in most cases acute dilatation of the stomach. Their condition was more alarming from the fourth to the eighth day than immediately following operation - the reason is obvious. About 6s per cent of all the fluid intake of the body

Is absorbed by the occum and ascending color The audden removal of this filter leaves the patient unable to pick up water until the left side of the colon has taken up the workusually from ear to ten days. If the patient during this time be given salt solution under the skin daily the convulsecence will lose all its terrors and become that of any major abdominal operation.

The importance of the choice of cases to be operated upon and the choice of operation in each individual case cannot be overestimated Improper selection of either is sure to be followed by defeat in obtaining the desired symptomatic results, as well as by post operative complication, which would be attributed to the surgery itself Ileocolostomy is designed to relieve a stasis in the fleum - the result of an obstruction preventing the free passage of its contents to the crecum. This has nothing to do with colon stasis or constinution and if a simple short circuit be done on a patient with constipation, a secondary colectomy will probably have to be done for impacted excum. We should not expect to cure a mechanical difficulty in the large bowel with an operation designed only to reheve a mechanical difficulty in the small bowel If a patient suffering from toxemia from the small bowel only becomes a surgical case I believe that the simple Lane short circuit is the operation of choice and I am sure it can be done with safety if the simple precautions against adhesions mentioned above are followed. If as is usually the case, the obstructed ileum is accompanied by a dilated crecum, which has lost the power to empty itself normally the Mayo right-sided colectomy is, to my mind the operation of The technique as developed in the Mayo clinic is free from the criticism of the Lane technique in that the intestines are not handled after the colon has been opened, and thus the possibility of infection is greatly lessened.

CIRCULAR CONSTRICTION IN THE TREATMENT OF FRACTURES OF THE LONG BONES

BY F IL PARHAM MD FACS NEW ORLEASS

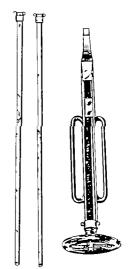

A T the meeting in December 1912 of the Southern Surgical and Gyne cological Association Mr Milne of the London Hospital showed a device for the fixation of fractures of the long bones. This consisted of a metal band with a screw thread its whole length along which a nut was made to move by means of a spanner as shown in Fig. 1 a b d and c. The band is thrown about the bone the one end passed through a loop at the other end and the band tightened by the spanner until the fragments of bone are held in place when the nut is fixed and the band cut off.

after getting back home I began to experiment to see if the apparatus could not be somewhat simplified. My aims were two first to find the best and simplest material to place about the bone and second to make as imple as possible the device for tightening the constrictor band. The second part of the apparatus was first elaborated on the principle of the €craseur or the wire snare. The constricting material was not so easily settled upon. I first tried silver wire doubled so as to form a loop at one end. The loop end was to be passed about the bone, the free end.

Fig 1 a b c d e Mil Instrument

carried through the loop and a perforated shot slipped over the wire. This being at tached to the tractor was easily drawn up and tightened by turning the traction screw and made as snug as desired about the bone. As the wire was tightened the shot was of course driven against the bone immediately over the loop and their mashed against it. This appeared extremely simple and theoretically seemed likely to answer all expectations. However in practice something always went wrong. We afterward twisted the wire which seemed especially to adapt it to holding

I'm 2 Puttl's Apparatus.

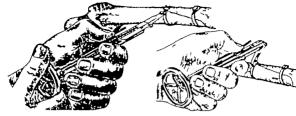

Fig. 3 Puttle instrument showing band tightened as about the carded over and caught between the t Putti instrument showing band tightened and lateral cars

For a Potto surviyoment showing tightening of band Surgical Association 30 cases thus treated He applied the bands in Boston last October be-

Upper band tightened and 1

itself in place about the bone but it was found that when sufficient force was put upon the wire to tighten it either the wire broke or cut through the shot, so that the constriction was lost. We experimented with different kinds of wire - copper aluminum, and bronze -but found none answered the purpose. Dr Martin suggested a steel band with a slit in one end expanded so as to make room for the other end to be slipped through. A hole in the other end made it easy to attach it to a pin near the end of the screw rod which was drawn up by turning the wheel at the other end. After various modifications in the perfect

ing of which we were cheerfully assisted by our instrument makers, the apparatus as finally elaborated and sold to the profession is represented in Fig. 8

I showed the apparatus before the American Society of Clinical Surgeons which met in New Orleans in March, 1914 and presented a femoral fracture treated with two bands Dr Martin shortly afterward applied two bands to a fracture of the tibia, holding the fragments so firmly in place that they were not displaced when in a delinum the following night the man got out of bed and walked about the ward (Figs. 10 and 11) Dr Lund, of Boston asked me to send

him one of the instruments shortly after this meeting and was able to report at the recent meeting 1 in Washington of the American

May rend (See fellering article in this series)

fore the Clinical Congress of Surgeons of North America, taking \ ray pictures of the cases immediately afterward showing the fractures reduced and the hands in place

Dr. Matas recently called my attention to an article on a new method of osteosynthesis by Professor v. Putti published in La Clinica Chiragica In this article Professor Putti gives a history of metallic ligatures in the treatment of bone fractures and describes an apparatus f his own which he had employed with success Cuts explain the apparatus fully. It will be observed that there is a striking imilarity between this apparatu and the Parham and Martin device

I did not know of his work until May i 1016 when Dr Matas called my attention to it as above stated. The suggestion of the Parham and Martin apparatus was derived as mentioned in the beginning of this paper from Mr Robert Milne of London. He subsequently showed his instrument and made

ults in breaking the wire at the critical moment. Futti was unable to overcome these objection. So he nnally turned to the metallic band to tening it obout the bone somewhat after the manner of a liphotic The tightening; done by a ban I neer with his illustrated in the a ompanying illustration Figs. 210.5.

The band is composed of an allow with a bronze base. It wares in width and thickness a cording to need. The 25 and 6 millimeter width ha been most used.

From the cut it appears that the fixer cat he she band whi his drawn up gradually by th long ser is worked by the wheel at the other end. The required tension being obtained the handle is carried toward beading the band through an are of about oo when it is cut off and the instrument removed. To avoid irritation of the tissues the band is arried between the two metallic ears just beyond the bridge of reflection through which the band has been passed (Figs. 2.3.4.5 and 1).

It will be observed that Putti's instrument is more complicated and cumbersome than the Parham and Martin apparatus requiring as it does a loop for making the slip knot and

tt apparatus (Putti

Fig t Fra ture of hum rus (Putti)

some remerks upon its use at Murphy clinic in Chicago. The remarks and cut are published in Murphy's Clinics for April 1913 to which I am indebted for the illustrations of the Milni apparatus here given

The Parham and Martin bands are intended for oblique tractures. If it is desired to apply them for a transverse fracture a plate or the girder of Mr. Souttar shown in Fig. 1 and two band, would have to be employed. This girder 1 a metal plate about a half inch wide bent along the middle parallel to its length to a little less then a night angle. A longitudinal shi is made in the fragments while held in apposition and one edge of the plate driven in until the wher lies flat on the bare urface. The band or two bands are then applied or the plate may be held in place by two or more screws.

The article of Putti is so interesting that I shall give here an abstract of it prepared from a tran lation kindly made for me by Dr Graffagnino of New Orleans

The metalli ligature one of the oldest methods of uniting bones should not be confused with the metallic sture which is limited in its application and should be definitely abundoned. The metallic ligature is based he thinks on correct principles and hould be considered the method of election for

8 P ham and Martin in trument and band.

Fig. c.

Fig. to. Dr Martin case.

Fig. Same case with two bands.

two lateral ears just beyond to hold the band in sits

In our instrument there is nothing but a silt in the expanded end through which the other end is passed. The tension of the band when tightened is sufficient to hold it in place

The band is of steel with a sufficient per centage of carbon to give it just the right degree of rigidity. The width varies from a to c millimeters.

It will be seen from a companson of the two instruments that ours is decidedly ampler being a simple band passed through a sit and clamped by simply holding it down flat. To cut it of requires only that it should be held fast by a chisel while the tractor is wiggled to and for a few times, when the band breaks readily. It is then driven down flat by a few taps of the mallet on the chisel pressed against it. The instrument is so simple that the whole operation may be completed with out once touching the wound (Figs. 8 10 11 12 and 13)

Dr Lund has devised a simple instrument for passing the bend and we have used a needle like a large ancurism needle which answers well. The band itself is easily passed

Fig. 5 Fig. 3

without any aid in some cases, but generally speaking it is difficult to do this as the band is not well adapted to moving about a cylindri cal bone surrounded by dense throus tissues, such as those attached to the lines uspera of the femur or the interoseous membrane of

the tibus Mechanically this band method is extremely simple and effective. I have not intended to discuss the question whether as W P Carr of Washington, asserts it really violates an essential principle in the treatment of fractures and actually interferes with callus formation. A most elaborate investigation published in the British Journal of Surgery has led Mr Hey Groves to conclude that in does and cats it does inhibit the development of external callus under and over the circular band but the work of Dr Lund which has been more extensive than Dr Martin s and mine, seems to show that practically the objection does not hold

THE PARHAM AND MARTIN BAND IN OBLIQUE FRACTURES

WITH REMARKS UPON MECHANICAL APPLIANCE VERSU BONE (RAFTS
BY F. B. LUND M.D. F.V.C.S. B. AT. N.

A S we gain turther experience and skill in the operative treatment of fractures we are more and more able to make an intelligent choice of the cases which should be operated upon early to operate more skilfully and take better after care thus avoiding the painful necessity of operating late upon the bad results of those fractures which have received the so-called conservative treatment.

In fractures of the lemur — particularly those cases in which the old Buck's extension treatment entailed for the patient so much discomfort and so long confinement in bed (three to six months) and for the surgeon so much care and constant adju timent of the apparatus — have our results been more satisfactors and the method of obtaining them more easy and comfortable both for the patient and the surgeon

In cases of transverse fracture of the femure specially those where repeated attempts fail to bring the ends into apposition and in which V rays show the ends overlapping or perhaps actually separated by a clear space interposition of soft tissue is the operation in dicated. We gain by operation with him internal fixation (1) the knowledge that the ends of the femurare in perfect position (1) the ability to hold them there by fixation in a plaster-of Paris dressing (3) the power to bid larewell to the cumbersome unsatisfactory and trying extension methods. We can also practically ensure for our patient a perfect anatomical result without shortening

The long plates with six or eight screws offer very good hixation in fimur fractures but the length of the limb and the power of the muscles are so great in proportion to the strength of the plate that without him long continued external hixation a slight springing of the ends may take place the screws gradually loosen and pull out and marked bowing or actual displacement of the ends occur resulting in failure. Of course experience has

by the time brought untruse wordscrew and to not them tightly in the crew hale but even with adequate technique fixation by plate and crew i not ab olutely satisfactory and long and careful immobilization in necessary.

Fiven though in plating our result are better than with the old method and our deformits be union so it much more rapid and in fact some (Martin) have claimed that it takes place more lowly and I think be iright.

In oblique and comminuted tractures we have a method of fixation which is implerable mechanically effective and get union in a comparatively hort time. I refer to the steel band devi ed by Parham and Martin of New Orleans.

Oblique and piral (or uncomminuted) tractures are perhap more trequent than transver e Transverse fractures are pro duced when the fracturing force is applied at right angles to the bone as when a man in an automobile accident is thrown ideway against a telegraph pole Oblique and spiral fractures occur when the force is applied nearly in the longitudinal axis of the bone, as in falls from heights striking upon the feet especially if the body be twisted so as to produce rotation. Sheerness of the application of force tend against transverse and for spiral tracture If we wish to break a stick transversely we pull it sharply acro-If we wish to splinter it we stand it on end and hit it with a mallet or twist it holding one end in each hand. It seems possible that a majority of fractures of the shatts of the long bones are more or less spiral or oblique at least we use the bands nowaday full as often if not oftener than the plates An obliquely fractured bone may be compared to a broken fishing rod the rod always breaks obliquely with a splintered fracture and the effective way to mend it i. to wind it with waxed thread thu, bringing the fractured surfaces in apposition and holding

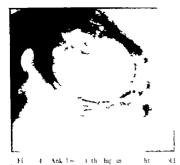

Fig. An oblique fracture of the femor, banded t years ago, in child, ged four years 4 (left), surerior view showing band embedded in the femore and entured overed by new periosteal bone B lateral view showing that here the bone has not entirely embedded the band.

them firmly The same principle is applied to bone by the Parham band. The bone if outside the body might be wound with copper wire as a fishrod is with thread and the result would be excellent. But this would take much time and cause much trauma in operating through a deep inclusion in the muscles of the thigh. A single wire passed once around the lone would not give firm enough apposition and would be likely to cut its way quickly into the cortex so as to be too rapidly loosened

The band of Parham and Martin is wide enough so that one or at most two of them passed around an oblique fracture give effective support and they can by means of the band placer be carried quickly around the bone and fixed as quickly as a wire can be rwisted. The rough oblique-fractured sur

faces are firmly held together and the frag ments evidently much more firmly supported than are the transverse fractures by a bone plate The strain on the plate is transverse and sometimes breaks it. The strain on the hand is longitudinal it never is broken after at is once in place. The firm apposition of the rough surfaces of bone prevents shoping twisting and springing Union takes place quite rapidly and motion may be allowed several weeks earlier than with the bone plate. The hand is wide enough so that it does not cut in and thus become loosened. It is simpler of application than the plates and screws as it requires no drilling of the bone accurate fitting of screws or careful use of acrewdrivers and drills. The one advantage in the plate and screws is that one does not always have to clear the soft tissues off clear around the bone, but can grasp the ends with heavy forceps and drill and put the plate in without clearing the soft tissues off the poste nor surface of the bone This is an advantage in the femur because the linea aspera is difficult to clear and it is there if anywhere that we get harmorrhage while in the tibia we must avoid the interesseous membrane and the occasional injury of the posterior tihial which may take place if we carry instruments carelessly around behind the bone slight disadvantage is not to be weighed for an instant in the oblique cases however against the other advantages of the bands A very clever instrument has been devised by Dr. Duff of Boston which may be passed around the bone while hugging its posterior surface and with the minimum of trauma and separation of soft parts which in my hands has greatly facilitated the passing of the bands. They may thus be quickly and simply anplied. In spiral fractures with comminution the band holds the separated piece firmly in its position between the main fragments of the shaft or if one band (as is rarely the case) does not accomplish this effectively two will certainly do so. For these cases before I knew about the bands I formerly used a plate and wires.

In our bospital we have a good many oblique fractures of the femur in children and three years ago I began to use the band on those

After banding and platter-of Paris fixation the patient have been urprisingly comfortable and the great advantage has been that no adjustment of apparatus has been required After four weeks the plaster can be taken off and after lying in bed a week the little patient get up on crutches and very soon are running The result in thee case have u, ually been perfect. When we fir t began to use the bands we were warned by various surercal wiseacres that in these children as the bones grew the bands would cut in and girdle the bone and that fracture would reult or that the band would cut off the nour Library from the distal portion of the bone and prevent its growth comparison being made to girdling a growing tree by a wire tight enough to cut off the flow of san and kill it But the blood and lymph which nourlh a bone do not flow traight up be tween the perio teum and bone as does the sap between the bark and wood of a tree from bottom to the top or the root to the The perio-teum from which the branches | surface of the bone 1 regenerated is nourished by blood vessels from all ide which are not cut off by the band and the marrow is nour hed by the branches of the nutrient artery which a it i protected by bony wall is not compresed or cut chi by the band None of my children who have had their

femur encircled by hands has suffered ub-

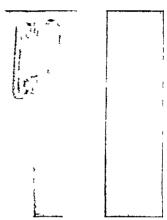

Fig. 8 lett. Ob 4 trasture i femur inth. 1 in i. 1 is a same trasture tie ted bithe band. This trasture wild has been i teemed, dish uffit it tre tib sten. wain tith anale twh thirbs haw mill bed. The was walkin in the level never a week.

sequent tracture and I am fortunate enough in one case to be able to present an Nray photograph (Fig. 1) of a femur in a child aged four year—about which a band wa placed two year—ago. The picture how the femur lightly widened at the point and the band included in the haft of the bone, which hapron that the band is hut up or enclosed in the bone and how it can cause irritation when irmly nized in rigid to see.

The question may fairly be a ked why we have not undertaken the inlay bone graft method in these tractures in order to d) away with foreign bodies and employ nothing but normal bone to us for historia.

The an_wer L that we have telt that in tractured temurs the muscle wound L nesses with so deep that it would be a difficult job to saw out the graft and that the use the band L so imple and cave a compart dwith the other that in fresh frictures on welld

hardly be justified in employing the latter method. The inlay bone graft also is obviously much better adapted to transverse than oblique fractures.

Fresh cases of fracture of the tibus it transverse can usually be brought into apposition without operation in fact they are usually the result of direct violence applied in a transverse direction and the tibula keepthem in place. In the much commonous spiral fracture the line of the fra ture does not favor the tiday graft while the band holds the surfaces in perfect apposition and must give a firmer support than would the mlay graft. An inlay graft would obvously be much ensier to saw out in the subcutaneous surface of the tibus than in the femure.

The non-operative treatment in spiral functure of the tibia never adequately gets the ends in apposition and there is always at least an inch of shortening. The results of the band treatment it seems to me leave little to be desired as the bone is restored princtically to its normal contour.

When plates are applied to the subcutaneous surface of the tibra, they usually have to be removed, as they are placed so superficially

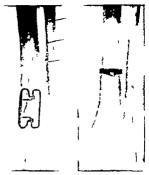

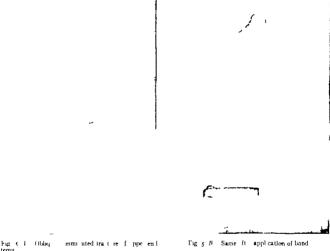

Fig. 4, 1 (left). Spiral facture of the tibia. and dol. B came, fer policition of band.

beneath the kin that thy ulcrate through by presure. However, band on the tibia har lives or have to be removed practically

never if the operation is asentic The ban Is are any field a foll w itudinal incisi n through the skin fascia lata and muscl exposes the fracture which is leared f periosteum, redu ed by extension and manipulation with the heavy Lane for cens in the usual way Then the peri strum is cleaned from the bon are und the central point I the line I fracture the Duff instru ment passed around the bone and the hand caught by the hold in the end and frawn around The end is then threaded through the I t the hole caught in the pin and the screw turn d until the band tightly engine The band is then bent harply the bone back by depressing the handle of the instru ment and the instrument freed and removed The band is then cut off close to the slot with wire cutters and the end hammered down The fascia lata is closed with a continuous catgut suture and the skin with silkworm gut without drainage. Smoothly applied sterile gauze and wadding and bandage plaster of

of temu

Paris spica to thigh. The bandage should extend from the toes to above the knee in case of fractured tibia

Six weeks in plaster is the time required for an adult thigh and four weeks for a tibia Stitches are removed in ten days through a window cut in the plaster. On removal of the plaster of Paris union is usually complete In femur cases the patient is kept in bed one week with the plaster off and then gets up on crutches There is usually some temporary ædema on removal of the plaster of Paris

Sepsis ought never to occur and may of course be in ured against by adequate If it does occur the wound must technique be opened washed out and drained but it may not be neces ary to remove the band for four to 12 week by which time bony union 18 complete. Infection may result in bad ad-

hesion of the muscles to the bone and in stiffness of the knee. It is a very serious matter and a reproach to the surgeon or hospital where it occurs With a competent and a well trained staff we can count on avoiding it but unfortunately we cannot always be certain where constant changes in assistants are made and an occasional in competent slips by as in many of our large hospitals

Since January 1 1914 I have used the bands in 14 cases and the Lane plates in , showing that in 66 per cent of our operative femurs the bands can be used. Since Jan uary 1911 I have plated 30 femurs I have used the bands o times in oblique fractures of the tibia and have not used the plates at all for the tibia since we had the bands I had previously used the plates for 13 tibias I

have never used the bands for the forearm bones, fractures of which 16 in number I have subjected to open operation since 1911 II were plated I wired I sutured (ole cranon) 2 open reductions, and I bone graft

The figures which follow have been chosen to illustrate cases suitable for treatment by the bands cases in which it would be difficult to get good and quick results by so-called conservative treatment Vote especially [Fig. 1.4] and B and Fig. 4.4 and B in both

of which a good and quick result was at tained

As a result of this experience and the observation of the cases of my colleagues, I believe that the Parham and Martin band is of very valuable assistance in the treatment of many difficult fractures, and I wash to express my dubt to the distinguished inventors and to say that it is not the only one of their contributions to surgery which has been of creat value.

NAILS AND SCREWS IN JOINT SURFACES

By ARTHUR T MANN M.D. FACS, MINN APOLIS
ASSESSED Professor of Surgery University of University Medical School

THIS senes of experiments was under taken after nalling a fractured and misplaced external condyle in the elbow of a boy of seven through the joint surface in order to determine the behavior of nails and screws so placed and the joint changes in response to their presence

This boy was referred to me si weeks after the fracture with the fragment still out of place, though the usual methods had been faithfully used to replace it I was unable to replace it by any f the ordinary methods and determined upon an open operation. After opening the joint we found the fragment rotated nearly one hundred and eighty degrees about a slight att chment to the external lateral ligament of the elbow and standing straight out from the joint Littl or no callus had formed and it was fairly easy to reduce it b t it would not at yin place It could not be made t t yin place either with the elbow at out angle flexion, t right angles, or with the arm straight. The head of the radius forced it out of place. We decided to nail it through the joint surf ce done Firm adhesions developed to the tissues bout the joint which later had to be broken up forcibly under ether. This loosened the fragment

good servicesible arm with moderate limitation at the extreme of motion.

The method described was suggested to me by an admirable article on joint fractures by Sherman and Tatt in the course of which they detailed some experiments with Lane s plates, bone pegs, screws and staples and in

somewhat from its bed but the final result was

the course of which they stated that after a painstaking search they could ind no case in the literature in which nails and screws had been used through the joint surfaces.

I think my series of experiments bring out some further points of interest.

In the whole series no joint became in fected and no specimen was lost. In most of them rubber gloves were used a few were done with the bare hands to see if the tech nique would stand this amount of exposure. No dressings were used after painting the suture line with tincture of iodine and the dogs were allowed to run about without fixation of the joints. Most of them favored the leg operated on for a time but as a rule they soon lost their limp and all of them were running about actively without a limp at the time the specimens were recovered.

Don No Soo Right's ce. Two nalls were driven in the inner condy! and counterpank less than the thick cas of the cartilage Moderate trauma was dided to the cartilage Moderate terms was elded to the cartilage and them. The nalls are cauties covered with a third layer of tiasue apparently of the same color as the cart of the cartilage. The cartilage is nearly smooth but not quate in the rea close bout the nalls. The semilumar and the joint cartilages re otherwise apparently smooth and normal, opposit the nalls as elsewhere. There is no staining it the beads of the crucial ligaments. Don N. 600 Left kare. A five-eighths inch diver plated screw was counterpush in the inner

F.g. L periment 650 right k ee 4 m. this 6 d. after operation. Two hall ou tersunk less than the thick eas of the til ge. N l entirely co-red with connective til ue.

condyle of the f mur well below the thickness of the cartilage. Three months less 2 days after operation (Fig. 2). A slight amount of blood was in the joint. The screw is entirely covered and the condyle apparently stightly built up about the screw area. The covering is not yet quite smooth and does not show quite as clear a translucent gray as the rest of the cartilage.

The cartilage on the outer posterior quarter of the other con lyte shows some thunning is a pale pink and the surface is not quite so smooth as the normal cartilage possibly from overnic due to a faulty position of holding the leg during the stages of convalencence. This was the only case in which changes suggestive of osteo-arthritis were present. The cartilage of the toblad head suggests a very slight similar hange while the semillurar seems normal. This was an old poorly nourshed dog and we came to the conclusion that this was probably present at the time of the experiment and not the result of the experiment.

The surfaces opposite the screw seem normal Though some blood was left in this joint the roots of the rucial ligaments are not as stained as in most of the other specimens practically none at the fem oral ends

Dog No 59 Right have Two nails were driven into the internal condyle of the right femurand countersunk well below the depth of the cartilage. Three months 24 days after operation (Figs 3 and 4). The nails are completely covered and the tissue is almost level with the joint cartilage slightly pitted but nearly smooth. The semilunar cartilage and the bearing surface of the tibla opposite the nails is perfectly smooth and normal. The cut six duce shows no apparent overbuilding of

plated screw was countersunk not quite the thick ness of the cartilage, into the conflyle of the left femur. A second larger drill was used to take care of the flare of the screw head. Two months so days after operation (Figs. 5 and 6). There has evidently been a slight upbuilding of the condyle about the screw. The screw head is entirely covered by a thin plate of tissue at a lower fevel than the joint surface and with the lower edge growing over the edge of the screw with almost the joint level. The opposing joint surface on third and semilulinar cartilages is smooth and normal The cast surface shows home beginning to grow inward over the top of the screw and is covered in turn by a thin cartilaginous or connective tissue.

Dog No 726 Left knee A silver plated screw was countersunk into the inner condyle of the left femur so that one edge was flush with the surface and the other edge buried one and one half milli meters below the surface. Six months less 2 days after operation (Figs 7 and 8) The surface of the condule has built up so that the free edge is buried The edges of the tissue have grown over the screw head burying all but one-fourth of is area and has grown way across in the groove of the screw joint surface is glossy and smooth at all other There is no roughness or inflamplaces in the joint mation of the head of the tibla or semilunar cartilag opposite. The joint is apparently normal in every oth r was e cept possibly the slight at nl g t the head of the inner crucial ligam nt. The cut suf c

new tissue is nearly smooth and apparently of the same character as the normal cartilage but in reality shows a connective-tissue structure. The groove which had been cut deeply through the semilunar cartilage the cartilage of the tible head, and into the bone has smoothed up and partially refilled in the six weeks. The surf ce is covered smoothly with cartilage looking like the normal cartilage of the joint surface. The joint cartilages are other wise smooth and normal. There is no taining t the heads of the crucial ligaments. The cut sur face. The ew increase in tissue seems, tirely d o to new bone. The new cartilage which covers this elevated area is no thicker than the thin cartilage of the joint surface.

CONCURSIONS

- 1 Nails and screws are tolerated in joint surfaces in the human as well as in the experimental cases and with surprisingly little reaction
- 2 They have remained firmly imbedded in every specimen recovered.
- 1 In every case where the nalls and screws projected above the joint surface, there was a distinct upbuilding of the condyle as Nature's reply to a rigid metal body projecting into the joint.

- 4. It is exceedingly interesting to find that the increase in sont level seems always due to the growth of bone and not to the increase in the thickness of the cartilage
- s In each case where tissue grew across over the head of a nail or screw or across in the groove of the screw the new tissue showed a reversion to the connective tissue type.
- 6 Even when the nails and screws have remained more or less uncovered the does have non about normally after a short convalescence
- 7 In each case the scratch or groove on the opposing surfaces was filled in as the projection of the null or screw lessened by the upbuilding of the condyle. The defect was apparently entirely filled in all but one specimen and this was closing in nicely at the end of sur weeks
- As a point in technique it seems better to swing a hinge joint freely at time of operation to scratch the groove made necessary by a badly placed nail or screw and thus save the time and pain which would be required in scratching the groove little by little later

NEW MECHANICALLY AND SURGICALLY CORRECT METHOD OF BONE GRAFTING

COMPARISON OF VARIOUS METHODS OF OPEN TREATMENT OF PRACTURES

By PAUL B MAGNUSON M D Croc. oo

LANE PLATE

C I CE Mr Lane stimulated world wide interest in the open treatment of fractures with the introduction and use of the steel plate screwed onto the outside of the shaft of long bones, there have appeared many and devious ways of holding fractured fragments of long bones in apposi tion by many forms of mechanical appliances. From a surgical standpoint, the Lane plate

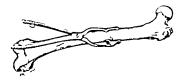

is deficient in the following ways

In most individuals steel acts as an urritant both to soft tissues and to bone with which it comes in contact, favoring infection by producing a collection of serum around

the plate and lowering the resistance of the tissues immediately in contact with it, if not actually killing them

2 The necessary length of the plate in order to secure proper leverage necessitates the loosening of the muscles from their attachment to the bone for a considerable distance on either side of the fracture, thereby producing unnecessary trauma and favoring infection

3 The screws used in Lane plate opera tions are of the wood screw type and it is necessary to use at least four in each plate to prevent the fragments from angulating pressure of these screws on the bone gradually

Magnuson lateral bone lamp n persti n Outline at nt dd holding fragme t ppun t graft show gwdth of med llary tsit ff one eighth inch wider at 1000sit

produces necrosis of the bone cells immediate ly surrounding them allowing the plate and screws to loosen in a comparatively short The allow the plate to move and further irritate the tissues both bony and soft which further produces a favorable field for infection

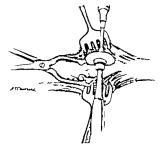

These are in brief the main objections to the use of the Lane plate from a surgical standpoint

From a mechanical standpoint the only bearing surface which the Lane plate affords in holding the bone in line is that which is provided by the small wood screws driven through the plate and into the bone This is a very weak form of mechanical union and when taken in conjunction with the fact that pressure of the screws produces necrosis of the bone immediately in contact with them we have double reason for not wishing to trust entirely to the support of a contrivance of this kind

In spite of these objections, there are some cases in which it is impossible to use anything but the Lane plate in repairing a fracture and one should always be at hand to suit the occasion no matter what plan is made before the operation

THE BONE PLATE!

The bone plate of Brougham and Ecke has the advantage of being non irritating and easy of application but has the disadvantage of the Lane plate in that the muscles must be disturbed from their connection with the bone over a relatively large area Brough in and J L. A prulmu up report on the treatment of urt, by fruition ath mound bose plates and bose serves. Surg. of LODAL 20.

I thors circular saw cutting sidgraft. F d or graft is ut with thin bladed husel or smaller saw with single handle. Note distance between 1 w of clamp all wing free mom t work.

claimed that this plate is absorbable author's experimental work however with both dead bone and ivory it has been shown that neither dead bone nor ivory are absorbed except where they are closely surrounded by bone The screws driven through these bone plates and into the bone cortex will event ually be absorbed only in such part as lies within the bone leaving the plates without any attachment except an incapsulating fibrous tissue which forms around them. The mechanical application of the plate to the outside of the bone throws an undue strain on a substance which is brittle and which is not braced on all sides and consequently subject to easy breakage

Brougham and Fcke have used the screw principle introduced by the author of tapping a thread in the bone and bone plate and using bone screws which undoubtedly hold much better than steel screws. The plate how ever is weak at the points where the screws are driven through it. The objections then to this form of apparatus are from a surgical standpoint the loosening of the muscles and production of extra traumatism in the applica tion from a mechanical standpoint its weakness at the points where the screws penetrate the plate

These plates however are improvements over the Lane plate and should constitute a

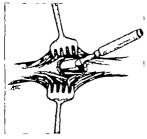

Fig. 3. Clamp removed and fragments slightly anyulated a slow insertion of graft int medillary cavity opposite fragment. The socket wrench, both a used is driving the screw is also used as an instrument to drive the graft in Dotted line shows the final position of the graft inside medillary carriy

part of the equipment of the surgeon doing any amount of open treatment of fractures.

IVORY SCREWS

In 1008 the author introduced the method of retaining fragments of bone in correct apposition by the use of ivory or bone screws The channel for these screws was first cut out by drilling a hole smaller than the screw to be used and tapping a thread within the bone with an ordinary mechanics tap This method has proved highly satisfactory in the treatment of oblique fractures of all kinds since it does away with the necessity of dissecting loose to any extent, the muscles attached to the fractured bone. The field of operation can be made small and trauma tism to the bone and soft tissues reduced to a minimum. The screw holds the rough ends of the fragment in close apposition not only in one plane but in all planes. It fits snugly into the hole made for it, but not so snugly that it produces necroels of the cells surround ing the screw The retention apparatus is small as compared with the size of the bone

Margamen Lengthering shortened brase of log Univ Pom M. Bull rook, May Ivney places and septem in the speed types most of bractions. J Am M Am not Dec. Lengthering short most of bractions for committee force A Obst. to 1, 278, 50

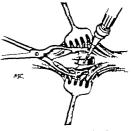

Fig 4 Fragments brought back int line Graft in place Drilling hole through graft and opposit aids of cortex preparatory to cutting thread for ivory screw

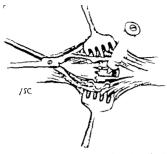

but on account of its mechanical construction which follows the lines of a machine acrew rather than a wood screw it has a long bear ing surface This screw is cut off flush with the cortex on both sides allowing nothing to project into the soft tissues to irritate them Neither the ivory nor bone screw will pritate the tissues with which it comes in contact This operation is simple and is easily and quickly performed. If the oblique surfaces of the fracture are long a screw at each end of the obliquity will hold against any pull of any group of muscles in the body not allowing angulation or displacement of the fragments and allowing early motion of the joints above and below the fracture.

One ivory screw has been used in the treat ment of a slightly oblique fracture of the femur on a number of occasions, with perfect results. An actuele to follow reporting a senies of cases of open treatment of fractures with the use of Ivory plates and screws will contain the \text{\text{\$\text{\$N\$}}} ray pictures and photographs of these cases.

From both a mechanical and a surgical standpoint the screw used in this way is an ideal method of treating oblique fractures.

IVORY PLATES

In transverse fractures it is impossible to use screws alone. It was therefore necessary

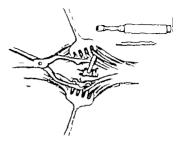

Lig 5. M ham a tip trod ed by th autholing oos used fir citting thre dain bone the same size as acrew to be used.

to devise some method which would meet the following requirements

- i Minimum traumatism in application
- 2 The substance must be non irritating to the bone and soft tissue
- 3 It must remain in situ without loosen ung
- 4 It must be strong enough to hold against strains in any direction and the constant pull of any group of muscles without allowing angulation or shortening

In order to meet the first requirement the apparatus must necessarily be small. It had been proved that ivory was non irritating to bone and soft tissues. It had also been proved that ivory did not loosen which was also true of dead bone. The fourth requirement - strength — gave ivory the preference over dead bone and it was therefore used instead of the latter.

The method used consisted in the cutting of a slot or as mechanics term it a keyway into the bone by parallel circular saws the slot being exactly the width and length of the plate to be used and extending across the fracture in the long axis of the bone the length of the largest plate being one and three fourths inches long and three ixteenths inch thick by one inch wide. A keyway and key is the strongest form of mechanical union known so far as a shaft is cincerned the key.

Ig 6 Souk tween hosed as screw driver square head diny screw screw being matried into gradition hold it in stiff to twee hit was taken

being braced on all sides but one by the mate rial into which it is driven. As long as this key remains in the Leyway and is fixed by pegs driven through the key and shaft at an angle to the key holding it down into the slot it is impossible for any motion to take place between the fragments of the shaft operation eliminates the necessity of loosen ing the muscles from the shaft for more than an inch on each side of the fracture reducing the amount of traumatism to a minimum The retention apparatus is very small and is as previously stated non unitating. The plate is driven snugly into the slot cut through the proximal side of the cortex only its lower edge being driven tightly against the medullary side of the opposite cortex. As in the case of the screws the application is snug but not tight enough to produce necrosis of the bone-cells immediately in contact with it The ivory being braced on all sides by the bone cortex has sufficient strength to resist all strain which is exerted on the fragments by the muscles and in the very nature of its application will not allow the slightest angulation

This operation has proved very satisfactory not oil; in the hands of the author but at this writing in the hands of many surgeons. Special instruments are needed to perform it but this is true of every operation as it is in other mechanical lines of work.

Fig 7 Cross section of graft through plane of acrew showing alot out of which graft was taken. Postilion occupied by graft in setullarly cavity and acrew through graft and cortex of opposite side bolding graft firmly in place.

THE INTRAMEDULIARY BONE GRAFT

The intramedullary autogenous bone graft as used and advocated by Murphy was one of the first forms of autogenous graft used in the open treatment of fractures. This necessitates cutting down on the tibia and remov ing the crest, reaming out the medullary cavity of the fragments above and below the This destroys at least part of the endosteum, delays union to some extent, and produces considerable hæmorrhage. The graft is then inserted into the medullary cavity of one fragment to almost its full length, the fragments being slightly angulated out of the wound and the graft being worked into the medullary cavity of the fragment not already occupied by it. This, of necessity makes a weak and loose mechanical union. It will hold the fractured preces from moving past each other but will not prevent angulation to a certain extent. The bone graft strikes the inside of the cortex at three points namely at each end and at the fracture. This gives a lever of the first class permitting any jolt or par to break the graft. or the pull of the muscles to gradually bend it, unless the external dressing is firmly fixed which is almost impossible in cases of frac ture of the femur rust below the trochanters.

This operation necesstates opening up not only the bone which has been fractured, but making a wound in the lower leg necessitating two operations instead of one.

THE BOYE INLAY

The bone inlay as advocated by Albee follows the same principles as the ivory plate the advantage of it over the ivory plate being

Fig 8 Longitudinal section through bone graft and screw showing position of graft in meduliary cavity. Slot left by excessor of graft, and screw bolding graft in place.

that it possesses bone regenerating power The objections to it are that it necessitates cutting down on the tible to secure the graft, producing extra traumatism of this bone and necessitates extensive cutting operations on each aide of the seat of the fracture loosening up considerable distances of muscle from the bone and cutting a considerable trough of bone out on both udes of the fracture.

As first described by Albee this bone graft was tied in with kangaroo tendon run through small drill holes at the edge of the slot, and through the edge of the graft. Sutures have never been a strong form of mechanical union in bone either in the shape of wire or kangaroo tendon or the like and it should be borne in mind that a severe strain by muscle pull is put on every fracture retention appar atus, whether it be external or internal. Albee has recognized this fact in his recent work by introducing the use of an autogenous bone screw put in in the way described by the author and already referred to The use of the autogenous screw is unnecessary takes a considerable amount of special equipment. lengthens the time of operation, and has no advantage over the ivory or dead bone screw since it is the bone graft which is depended upon to regenerate bone at the seat of frac-This procedure then is superfluous. It is impossible without producing tremendous traumatism and harmorrhage to cut out a key of bone and fit it into a full length slot as described by Albee in the case of a femur or humerus, and these are the hones most frequently necessary to treat by open operation.

It is also practically impossible without producing tremendous traumatism to cut a long slot on one side of the fracture and a short one on the other moving the long piece of bone down across the fracture and using the short piece for the purpose of making bone screws as described by Albee without freeing the muscles from the bone for a considerable distance on each side of the fracture producing a great deal of hæmorrhage both from the muscle and bone and lengthening the time of operation and shock thereof to an unwonted extent. This operation can be done very nicely on the tibia where the bone lies immediately under the skin and where there is no muscle to contend with. Consequently favorable reports of this sort of graft in the tibia mean comparatively little.

It was to correct the defects mechanically and surgically in the bone grafting operation that the procedure next to be described was devised. The requirements were (1) To secure an autogenous graft as small as possible to assure firm retention of the fragments (2) to eliminate the necessity of traumatizing other fields than that of the fractured bone (3) to shorten the time of operation and (4) to place the graft in the bone in such a way that it would prohibit motion in any direction and hold against any pull crefted

on it by the muscles attached to the shaft This was done by cutting a short graft from the fractured end of the most convenient fragment either proximal or distal graft was cut in the shape of an extremely long sided truncated cone. The end of the graft which formed part of the fractured sur face is exactly the width of the medullary cavity and the end farthest from the fracture not over an eighth of an inch wider than the medullary cavity the graft being from one and one half to two inches long and covered by periosteum. The sides of the graft being cut out with the circular motor-driven saw the end of the graft is freed with a thin bladed chisel The opposite fragment is then angulated slightly out of the wound and the graft driven in to the end of the medullary cavity to half its length. On account of its wedge shape it fits snugly. The fragment is then brought back into line with its fellow and the protruding end of the graft is drive Thi down into the slot out of which it came being the wider end allows for the thickness of the saw blade on each side and yet allow the graft to come closely in contact with th walls of the cortex on each side and sink dow into the medullary cavity. The result nov is that one end of the graft is firmly driver into the end of the midullary cavity of on fragment the other end being driven into th lower and of the slot out of which it came There is no way of angulating these fragment except by one end of the graft slipping out o the slot or keyway. This was provided against by drilling through the graft and th opposite cortex tapping a thread in the bon and putting through an ivory screw which holds the key firmly down in the keyway The screw is then cut off flush with the graft leaving nothing protruding beyond the corte on one side or the graft on the other and leaving a one inch trough above the graf to be filled in with new bone

This operation has been extremely satisfactory in the hands of the author and a few other surgeons who have seen fit to use it It does away with the necessity of cutting into any other bone to procure the graft and meets all the mechanical requirements of strong union. There is not as much loosening of the muscles as there would be in a Lane plate operation but somewhat more than in the ivory plate operation. In cases of un united fracture the bone graft is preferable to any dead bone substance.

The technique described shortens the timo of operation lessens the shock and doc away with a large amount of the hamorrhag which occurs when the graft is taken from the tibia. Therefore we beheve it meets a the mechanical and surgical requirements of the internal splint and that it will be fount to be much more satisfactory than the methods heretofore advocated.

A CONTRIBUTION TO THE ETIOLOGICAL STUDY OF OVARITISA

B CARL HENRY DAVIS, M.D. CHICAGO

From the Memorial Livelents for Inductions Ductors and the Department of Obstactics and Gymeniogy Rush Medical College

LABORATE studies have been re corded giving the histological changes which occur in acute and chronic ovaritis The bacteriology of acute ovantis has been studied extensively but heretofore little has been accomplished in the cultural studies of the chronic inflammations associated with aderosis and cystic degenera. tion. The newer bacterological methods as emphasized especially by Dr Rosenow have made this study possible. That some of the acute infections of the ovary may be of hamatogenous origin and not a direct exten sion from the lower genital tract was suggested by Lawson Talt many years ago and is supported by many recent chilical observations Rosenow has demonstrated that bacteria from foci of infection and the involved tissues in various diseases from which the streptococcus is recovered, such as appendicitis, ulcer of the stomach, cholecystitis, erythema nodosum and herpes zoster tend to infect electively the corresponding organs in ammals, when injected intravenously and recently he has shown that some of the streptococca which we recovered in chronic inflammation of the overy showed elective affinity for these structures in animals.

Using a technique which has been described in other papers, Dr Rosenow and I have cultured 65 ovaries. In three of the patients the condition was rather acute and in these the streptococcus viridans was recovered twice and the gonococcus once, The other patients had chronic pelvic disorders. In ten cases the cultures remained sterile after a week s incubation. In the remaining 52 cases in which the ovaries showed fibrous and cystic degeneration, streptococci were isolated 30 times, the number of colonies ranging from one or relatively few usually in the depths of the ascites-dextrose agar to countless num bers. They were present in pure culture in 8 and associated in the others with the Welch bacillus a few staphylococci or colon bacilli. Welch bacilli were found in small numbers in

21 diphtheroid bacilli in 10 a few colonies of staphylococcus albus in 9 the gonococcus in 2 the colon bacillus in 3 and an anaerobic streptothrix in 1

The associated abdominal conditions were carefully recorded in 56 of the histones. Fibromovom of the uterus was found in 18 patients, and the ovanes from 15 patients gave positive culture—the streptoeoccus viridans being isolated from 11 and the Welch bacillus from 8. Salpingitus was reported eleven times, and the ovarian cultures were positive from 9 streptoeoccus viridans in 8. Welch bacillus in 3 and gonococcus in 2. Chronic appendicitis occurred 11 times and the streptoeoccus was recovered from 8 of the ovaries. Eight patients had a chronic chole cystitus and 6 of the ovanes cultured contained the streptoeoccus vindans.

Only a few of the women with chronic ovaritis gave a history of a preceding acute pelvic infection. In a number it seemed evident that the pelvic symptoms were the result of contracting a cold during the mensional period or followed definite attacks of tonsillitis. In others the pelvic symptoms were subsequent to some one of the acute infectious diseases of childhood While many of the women were married and more exposed to the conditions producing ascending infections a number were undoubtedly virgins and in at least one patient, in which the ovarian cultures showed the streptococcus, the possibility of an ascending infection can be definitely eliminated.

MICROSCOPIC ANATOMY OF THE HUMAN

The microscopic changes were such as have been described in the extensive studies on hisrocystic degeneration of the ovary and do not call for detailed description. With the help of W L. Brown, 16 additional ovaries have been studied since the joint report with Dr. Rosenow making a total of 39 ovaried which have been carefully examined. In a

Real before The Checups Gyneralogical Sectory April 916 (See decembes 9 635)

number these were remnants of follicles which were largely replaced by connective tissue and surrounded by round-cell infiltration The stroma in all showed marked fibrosis and frequently small relets of the interstitual cells The blood vessel walls were thickened walls of the small cysts were intiltrated with numerous round cells while the walls of the larger ones were made up of old connective Nests of round-cell infiltration were found in many chiefly surrounding the blood vessels and in the walls of the granfian follicles. In a number aggregations of leucocytes were found within and around small blood vessels especially in those in which the portion cultured showed a relatively large number of streptocccci

To demonstrate the bacteria in the tissues was extremely difficult but in Lections from cleven ovaries including the eight previously reported where the cultures showed a large number of the streptococci Gram Weigert and methylene blue stains showed diplococci They were found usually in the areas of infil tration and in at least one case in the wall of a corous luteum

Discussion Lawson Tait in his monograph on Diseases of the Oraries says know acute ovantis is the result of four diseases only

- Injury
- Conortheral infection
- 3 Septic poisoning in the parturient condition
- 4 Exanthematic fevers and acute rheu matism

Thus it is evident that Tait recognized nonascending acute infections of the ovary de pendent upon the exanthematic fevers and acute rheumatism even though he had no knowledge of the bacteriology of these conditions He says In 1870 and 1871 and still more in 1874 my attention was drawn to the occurrence of acute pelvic peritonitis in women after attacks of scarlet fever and small pox these attacks leaving indications which showed clearly that the mischief began in the ovaries Accident enabled me to trace the subsequent history of two such cases and I found that in both the menstrua tion became greatly diminished in amount

and that it was accompanied by severe dysmenorrhocal symptoms and that in one of the cases it entirely disappeared. From these cases I began to suspect that the attacks were primarily due to inflammations of the uterine appendages and that this had some Lind of relation to the zymotic disease which preceded it Later he writes I have only once had an opportunity of dissecting a case where I had recognized chronic ovaritis in life and then it certainly was the result of acute rheumatism. It occurred in the case of a girl seventeen years old who had suffered from eight or nine attacks of rheumatic fever In two of them she was under my care as a dispensary patient and after the recession of the particular infection an attack of pelvic pain came on which was increased by pres sure and the attack was accompanied by an irregular menstrual flow. The whole passed off in a few days after the application of a blister but ever afterward her menstruation was irregular profuse and painful and she suffered from the symptoms which I shall describe immediately I regarded the attack as one of mild acute or subacute ovantis followed by a chronic stage. She died subsequently of embolism of a cerebral artery and I found her ovaries large soft covered with lymph and dotted with enlarged follicles and the peritoneum was thickened around The left ovary was adherent to the rectum and it had nearly the whole of the fimbrie of the corresponding tube glued to it.

It has long been recognized that mumps are apt to cause orchitis in men and ovaritis in women But Joel in 1886 called attention to the occurrence of orchitis in boys and ovantis in girls following tonsillitis For gen erations women have recognized that to take cold during a menstrual period was apt to result in a suppression of the menses with subsequent dysmenorrhoea and often pelvic Our textbooks all recognize this fact but I have never leen a satisfactory explana

The recent writers of books on gynecology all recognize the possibility of non ascending infections of the ovary but they apparently believe that most of the infections are ascend Dr Webster writes (p 365) on the etiology of acute ovaritis Various infective conditions e.g especially infection follow ing abortion or labors gonorrhoes, pneu monia, mumns the acute exanthemata. tuberculosis actinomycosis And etc. (p. 366) Chronic inflammations of the ovary may be the sequel of an acute attack such as has been described or it may develop slowly with no definite onset Active conpestion displacements and twistings are favoring conditions. It is frequently secondary to infectious processes in the uterus and tubes. It is very frequently associated with fibromyomata of the uterus and large ovarian tumors of the opposite side. Of all the causes gonorrhera is one of the commonest. It may be secondary to appendicitis Chronic ovaritis may be the terminal stage of an acute infection of the ovary Any condition causing prolonged congestion of the ovary will result in chronic ovaritis such for example as sexual excesses, men strual congestion, subinvolution malposi tions of the uterus, habitual constipation incompetency of the cardiovascular system, pelvic and abdominal tumors, and the disorders of the organs of digestion made a careful study of 180 cases operated on for cystic ovaries by Dr Webster and himself He found that The usual infec tious diseases of childhood were experienced in 65 per cent af the 180 cases and there was a history of puerperal post abortive, or conorrhogal infection in 63 per cent. believes from this study and a review of the Cystic degeneration of the literature that overnes is almost invariably the result of This is the consensus of chronic ovaritis. coinion of Virchow Gebhard, Abel Kolb Ruce Pfannenstiel Amann, Martin and Frankel (Findley)

Wilder in a recent paper presents strong evidence that acute streptococcic ovantis may follow the streptococcic sore throats. He quotes three typical cases reported by Leyden, Kunzel, and Schwers, and adds a fourth personal observation. In these four cases there can be little doubt but that the acute infection of the ovary was blood borne and in each case secondary to the infection in the throat. Yet with the normal genital

tract it is almost impossible to prove from the study of the cases that the infection could not have been ascending. But this clinical evidence is proved by the case in our series in which chronic salpingo-ovantis had developed in an eighteen year-old girl in whom there was no passage between the vagina and uterus. It is further strengthened by a case in which there was a congenital stenosis of the uterus with a double cavity. The cultivation of streptococcus viridans from the ovarian tissue in these cases, the demonstration of the organisms in sections of these ovaries the experimental production of ovaritis in animals, and the finding of the organisms in their ovaries explain clearly how a patient may contract chronic ovarities without a preceding infection of the lower genital tract. While allowance must be made for the possibility of direct extension of infection from some other infected organ such as the appendix, the finding of the colon bacillus in only a cases is good evidence that chronic ovaritis can be but extremely rarely if ever due to organisms which have passed through the normal bowel wall

While the experimental work explains the importance of the streptococcus in ovarian degeneration, the significance of the Welch bacillus in one-third of our cases is not so clear Since this organism is found so fre quently in the cultures of tissues of carnivorous animals it has been thought that it is as the rule, a rather harmless invader Williams states that the bacultus aerogenes capsulatus is occasionally concerned in puer peral infection and several cases have been reported from his service at the Johns Hookins Hospital In our series a pure culture of the Welch bacillus was obtained from the overv of a woman who had suffered with puerperal sensis but while the ovarian trouble dates from the sepsis it may not follow that this organism was responsible for either the degeneration or the preceding sepsis.

From our cultural studies of 65 ovaries it would appear that the streptococcus vindans is the most common organism associated with the chronic degeneration of the ovaries being found in approximately 50 per cent of the cases. The Welch besigling was found

Fig 1 Drawing f pecumen Case one

in 33 per cent but is probably of little import ance. Other organisms are apparently found rarely in the usual chronic degenerative changes of the ovary. While the gonococcus is undoubtedly a common cause of acute in fections of the ovary it is not found in the more chronic conditions and our results suggest that some of the chronic pelvic conditions which were formerly credited to the gonococcus may have resulted from non ascending infections with the streptococcus varidans.

The fact that ovarities is so much more common than is orchitis is of considerable significance. Wilder in his review collected 56 cases of primary peritonitis probably all of the streptococcic type of which 44 or nearly 80 per cent were in females believes that in most of these that the pri mary infection was in the ovary and the pentonitis secondary. It has been suggested that the corpus luteum is often the point of inoculation Certainly the fact that women are so prone to infection of the ovary at the time of menstruation is a strong argument in favor of this suggestion. That the tube may become infe ted from the ovary or the ovary from the tube is generally accepted and it is also probable that both are infected simul taneously from the blood stream in some cases of bacteremia

The following two case which were reported in the joint paper with Dr. Rosenow art of so much importance in the discussion of this subject that they must be included in our case histories.

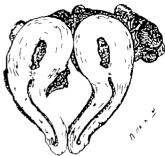

Fig Drawing of specimen Case 960

Case 660 A girl of 18 years ent red the Presbytanan Hospital complaining of a dull heavy a ching pain in the right Inguinal region which recurred each month during the past year lasts three days and then disappears. Sh has never menstruated At the operation Dr Webster found an imperforate vagina one inch long the uterus was retro-cred the cervix lay posterior to the vaginal wall and was only attrched to the corpus by means of a abrous band there was considerable thicking of both tubes with closure of the right hibrous and cystic degeneration of both ovaries especially the left and adhesions about the rectum and appendix. He did a modified panhysterectomy and appendectiony.

A drawing of this specimen is seen in Figs. r and 2 Twelve colonies of streptococcus viridans were grown from a portion of the left ovary and a diplococcus was demonstrated in the sections.

CASE 3 3 A single woman age 30 entered the Presbyt rian Hospital on the servi e of Dr Billings July 20 1014, complaining of multiple enlarged swollen tender painful joints and muscles par ticularly the jaw elbows hands and feet with marked limitation of motion and fixation. arthritis began three years before some weeks after a severe attack of tonsillitis. There had been recur ring exacerbations and remissions of the symptoms but on the whole they had at adily progressed Sh had lost 30 pounds in weight during the past year and a half and in the past year had developed a se ere dysmenorrhum. Cramps an I nausea had lasted throughout the period and often for eight or ten days following L cept for frequent attacks of tonsillitis and a chronic rhinitis the patient had been in fairly good health until three y are before when she had the attack of tonsill tis with an abscess of the tonsil. The tonsils we removed

nine weeks after the arthritis began and she im proved greatly She had measles and whooping cough in childhood. During the past year she had been curetted twice for the dynnenorrhoes without relief The patient had good appetit and slept well. The bowels were regular there was n urinary disturbance no leucorrhora at the time of examination, no cough, no dyspaces, no night aweats, no ordema of the feet no cardiac or gastric disturbance no jaundice no diarrhora, no chills or fever. The examination was negative except fo the condition of the joints, the finding of small remnant of the left torsil, and some bad teeth. ray of her hands showed that there was complet ankylosis of some of the fingers, with marked destruction of the cartilage in the balance of the loints. The remnant of the tonsil was removed and the condition of her teeth rectified. The patient left the hospital and returned again in January The symptoms of the arthritis had greatly improved but she complained of excessive menstrual flow for which she was curetted by Dr Webster but without

relief reuer
On March 23 10 5, D Webster removed the
left ovary ligated the uterine arteries, emoved th
appendix and a small fibroid from th back of the Cultures of th overy were mad Dr R O Raulston and the streptococrus vindans obtained in large numbers. Dr Rosenow injected sub-cultures into three female dogs and four female rabbits in doses ranging from 4 t 95 cubi centi-meters of the broth culture suspended in salt sol tion. All but one rabbit recovered. Th animals were chloroformed o the second and third days after injection. All of th animals injected showed lesions of one or both ovaries. Five showed in addition distinct arthritis on myositis one holecystitis and two hemorrhages and ordema of the thymus. Three showed lesi as in the uterus, and one hemorrhage in the fallopian t bes. Filtrates of this broth-culture, on the other hand, injected into two rabbits in equivalent and repeated doses failed ntirely t prod to lesions in the overy or otherwise.

Following the operatio in March, the patient a general symptoms were much better b t the menorrhagia soon returned and on October 5 o 5, D J C. Webster removed the uterus and remaining overy Cultures of this overy were mad by Dra F Gaarde and G Coleman and the same organism was again isolated. This injected into rabbits produced arthritis, b t unfortunately their ovaries were not examined for lexions.

When seen on March 5 10 6 the putient stated that she had gained twenty pounds in weight and that she feels much better in every way She still

has joint pains but less severe.

The following histories are chosen from the cases cultured because of the large num bers of organisms found in the cultures and the variety of associated conditions

00180. Mrs D ge 24 entered the Presby t rian Hospital, Novembe 915 complaining of weakness, a constant feeling of tiredness, headaches, backache, pain in the lower right quadrant of the abdomen, lencorroces d constinution.

During the past year she had felt tired and weak all of the tim especially on arising in the morning. During the past four months he had been unable to work. She has had severe headaches during the past f ur months, fro tal in haracter dull aching in type. d present nearly il of the time. They are especially severe in the morning and are gradually growing worse During the same period she has had a dragging backache For over year she has the right lower quadrant of the had some par abdomen Four mo the ago it was very severe but of late it has been causing less trouble. She says that there is a feeling of sorepess which comes

whenever she is t red and is always worse during the mensurual period. During the past four years she has had marked leu orrbera. Two years ago it was most severe but is better ow. During the past three years she has had marked consupation. The patient says that she has had no sickness other than the diseases of childhood.

She was married 5 years ago but has been sepa-rated from her husband for years. She had one pregnancy 3 months after marriage and aborted. The writer diet ted the following findings at

the operation Numerous adhesions between the terus and the rectum holding the terus in retro-version. The left ovary is bout the siz of a small English waln t and is buried in film of adhe sions The left tube is somewhat thickened. The right vary and tube are buried i dhesions and fastened to the brim of the pelvis. The ovary is moderately enlarged and markedly cystic. The appendix is 4 inches long slightly thickened, but free from adhesions.

Operatio Freeing of pelvic dhesions. Right luingo-oonh rectomy Webster round ligament salpingo-ooph rectorny operation. Covering of the raw urfaces in the pelvis Appendectomy Cultures of the right ovary showed many colonies of streptococci. Mrs. D reports March 26, 0 6 that she is fee from pain, has no headaches or backaches no consti pation. She is at work i an office d whil sh

still tires easily feels perfectly well.

No 90236 Mrs. R. C age 49 married ten

pregnancies, no miscarriages o abortions.

The patient complains that during the rear she has had considerable pain in her back, intermittent in character present during the day but not at night. The aching is we rise when she is on her feet, is relieved by massage and by lying down. It has steadily been growing worse. The menstrual flow has steadily increased in am unt during the past 4 or 5 years but has not increased in duration. The abdomen has been increasing in size during the past 4 years until now it has the appearance of a 5 or 6 me the pregnancy. There has been some loss in weight. During the last 3 years ahe has had a severe leucorrhoca. Her past history is negative. Her family history is

negative Habits are negative

Dr. Webster dictated the following findings at the operation. The uterus is enlarged by tumor mass 8 inches in diameter. Both ovaries are cystic There is a simple cyst of the left ovary 2 inches in diameter. Gall bladder is free and normal. Right kidney is scarcely movable. Left kidney is scarcely movable. Stomach is normal. No nodules or enlarged glands are found in the upper als/domen.

Operation Supravaginal panhysterectomy The tumor was found to be an interstitial hibroid of the uterus which had undergone a myxomatous degeneration. The sections showed no evidence of malignancy. Cultures of the ovaries showed many

colonies of streptococci

CAST 5 248 Miss S age 34 entered the Prebyterian Hospital June 1910 complaning of constant backache constant tenders as in the lower abdomen leucorrhaa, and general wakness having been in bed most of the time during the past three years Rowels are regular Menstrua tion is of the regular 23-day type preceded by soremess in the breast for ten days slight dysmen orthose Has cold chilly sensatin most of the time Has no unnary disturbances. No history of sick neas other than the diseases of childhoot

Operation June 22 1010 Dr Webster dictated the following indungs Uterus is retroposed 3 inches deep and dilates with difficulty Prolapsed in flamed degenerated ovaries. Marked adhesions in the pelvis. The appendix is thickened

Operation Dilation and curetage removal of the left tube and ovary agusection of the right tube Webster round ligament operation appendectomy. The patient had a normal temperature when she entered the hospital but following the operation her temperature with the control of the time during the following week. Her pulse varied from 2 to 100. She was discharged in good condition July 12 21010.

Muss S enfered the hospital again June 14 1914 complaining of pain in the right lower quandrant of the abdomen nervousness and general weakness. She stated that the pain is worse during the men strual period. She has not been very much better

since her operation four years ago

Operation June 15 1015 Dr Webster dictated the following findings. There are adhesions of the omentum along the anterfor abdominal wall. The right ovary is enlarged cystic and fastened with a linesions. The uterus is adherent to the rectum and bladder. The gall bladder is normal.

Operation Hysterectomy and right cophorectomy. Her temperature went to 100 5 the second lay after the operation and varied between oo and 100 during the hist in days after the operation.

Novembe or S Miss's report that he is free from pelvi and abdominal pain. I has ally she

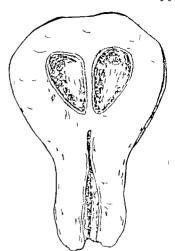

Fig. 3. Somewhat schematic diagram. Case 55722 Mrs. M. aged o. Since her I treemth year she has had subjective ymptoms of menatruation every. 8 days. Had a laparotomy when fifteen. Both tubes and one overy remo ed. Had abdeminal dramage? f ur da a. During past yea she has had littl potting with pelvic cramps on two occasions b.t. has never necessituated.

Operation by D Webster recealed dense pelyor adhesions with loops of boxel attached to the uterus and remnant of the left ovary. Section of the terus revealed the congenital malformation as hown in the bove diagram. She was operated during an attack of so called menatural pain and fresh blood was found in both cavities of the uterus. The endometrium was very thin and showed no evidence of inflammators changes.

is perfectly well but states that she suffers from attacks of melancholla and that she often has severe headaches in the top of her bead. She feels particularly bad in the morning but as the day passes she gradually loses her depressed feeling provided she is with cheerful company and u unliy feels good in the ev ning. She does not suffer from hot flushes and ne er bas ha! them

She states that as a grd she was subject to ton silitis but that the tonsils have not bothe ed hir for many year. This pelic trouble turted with a severe cold contracted duning the minimal period.

and gradually became worse. She was a chronic invalid for about twelve years.

Miss J W age 24, entered the Hospital Miss J S complaining of swellings on each side f the lower abdomen, pain in both lower quandrants of the abdomen, tendemess of the right breast. The patient states that she was perfectly well until about fourteen months ago when she noticed a marked locress in the pain during the measural periods about the same time there popured on High in the time of the pain of the same time the pain of the pressure of the clothing to the touch and to the pressure of her clothing to the pressure of the clothing to the pain of the pain of the pressure of the clothing have penisted and are still tender to the touch.

The pain is bilateral b t more marked on the right side. It is usually of a dull aching type but occasionally the has ttacks of sharp sticking pain. These occur at intervals of four to it days. These ttacks are very brief, lasting but min t or two and they do not radiate. About six in the ag ber symptoms were so marked that abe was coolined to the cooline of the c

Her past history is negative except for measies and whooping cough as a small child and some kind of a fever at the age of nine. Menstruation began at years, regular 28-day type of 3 days duration nill one year ago when she began t flow for two

days skipping a day with return for two days. The pain is Increased during the periods. Dr W bater dictated the following Gail-Madder normal, Idineys eith ave a 28-inch range stomach normal appendix 7 inches long and faste ed with adhesions, uterus enlarged by a tumor mass (fibronyoms) 4 inches in diameter right tube thick ed in the middle part, right overy abows chroni-cystic degeneration but is not much enlarged, left ovary

has the same conditi n.

Operation Appendent my supravaginal panhysterectomy. The patient's temperat went to 10 a few hours after the operation but never went over or s.7 and returned per and after four days.

SUMMARY AND GENERAL CONCLUSIONS

From a cultural study of 62 ovaries showing the changes found in hirocystic degeneration and three in which the process was more acute the findings of the streptococcus viridans in 50 per cent of the cultures suggests that the streptococcus viridans is the most common organism associated with chronic ovarietis. Since the cultures from ten ovaries remained sterfle, it would appear that chronic degeneration may result without the presence of bacteria or that the bacteria are gradually killed and the ovary rendered

The findings of the gonococcus in only one acute and one chronic ovary would seem to indicate that this organism may not be responsible for as much of the chronic ovarian disease as was formerly supposed Although the Welch bacillus was found in small numbers in 33 per cent of the cases yet in the absence of any definite animal experi ments it may be considered a more or less harmless invader still it must be remem bered that this organism has been the cause of puerperal sepsis. The staphylococcus albus and the diphtheroid bacillus are regarded as accidental or harmless invaders since intravenous injections of each do not produce lesions in animals.

It has long been recognized that the chronic ovarian degeneration may follow acute infections of the ovary and this study shows that bacteria must also be regarded as the etiological factor in chronic ovantis though it has developed without a definite history of an acute infection. The various conditions which cause passive congestion in the pelvis are to be considered as predisposing and not as etiological factors.

The not uncommon history of pelvic trouble following anginal stracks during the menstrual period the occurrence of pelvic infection following immediately after tonsillutis the discovery of chroale tube-ovarian inflammation in a young woman with a congenital atenosis of the cervix and the uterus, with an imperforated vagina and the isolation of the streptococcus viridans from her left ovary together with the experimental production of ovaritis in animals seems conclusive proof that hematogenous infection of the ovaries occurs and that it may be responsible for much of the chronic ovarities in which there is not a definite history of genoritheas or

puerperal sepas.

The find of bacteria, especially the strep-tococcus viridans in the greater portion of the ovaries cultured offers a logical explanation for the not infrequent recurrence of cystic swellings after resection of the ovary It also suggests that the ignisection or drainage through a single opening with Paquella s cautery as practiced by Dr Webster may be the method of choice since

the heat may kill the bacteria. This study also shows a probable reason why transplanted over the degenerate.

A study of the til ues together with a careful review of the histories gives no new or definite mean for choosing between a conservative and a radical operative procedure. Since some ovaries are tende and many other contain only a few organism. the writer believes that this study tax r conservation of the oxage whenever the operative findings will permit. In thi series it was usual to find rather large number of streptococci in the ovaries of patients who came to a second operation With a young woman it is better that she come to a second operation than to lose both ovaries the first time even it there is an equal chance that con_erved tissue may degenerate

The indings of bacteria in niteen (eleven of which showed streptotoccu viridans) of the eighteen degenerated ovaries associated with nbroids of the uterus suggests strongly that bacteria are likewise responsible for the chronic ovaries so commonly associated with nbromyomata.

Since there appear to be very trequently some rather definite connection between the

more common 15c1 of chronic infection and ovarity, it evident that in treating a patient with ovarian trouble that any such four hould be 15 ated and removed. It would eem logical to believe that by the early detection and elimination of these primary injection of might be possible to less en the occurrence of syaritis.

I will have a cknowledge my indebtednes to Dr. J. Clarence. Web ter for his uggestions and the privilege of reporting his cases, and to Dr. E. C. Risenow for his co-operation in this study.

THE LEUCOCYTES IN PREGNANCY LABOR AND THE PUERPERIUM!

BY JOSEPH L BAER SM MD FACS CHIC GO

AFTER Nase had called attention to the existence of a true leucocytosis of pregnancy numerous workers be gan checking his results at his with widely varying outcome but smally with utilicient unanimity to warrant the statement that there is a leucocytosis of late pregnancy especially in primiparse

The physiological leucocytosis of labor and the purperium is generally accepted without debate but in clinical practice the question constantly arises. Is the leucocytosis in the given cale physiological or pathological. To supply a working answer to this question and to establish a standard of

comparison for the leucocyto is and differential analysis of pregnancy labor and the puerperium the following study was under taken at the suggestion of Dr. L. E. Frankenthal utilizing the material afforded by the Michael Reese Materinty.

The literature abounds with investigations of this kind and each worker has laid stress on the errors of his predecessor. For example it is pointed out that counts should start on the pregnant woman and be carned through on the same woman in labor and the puer penum that comparisons on different women at different periods introduce an avoidable error that the figure of interest is the in

crease in the leucocyte count over the normal for that woman not the actual count itself that the figures are complicated by the introduction of abnormal cases into the series that the influence of digestion was ignored

Among the earliest views is that found in Virchow's Cellular Pathology He states that there is a monthly increase in the leucocytes in pregnancy which is proportional to an increase in the lymphatics of the uterus, and an increase in the lymph nodes of the inguinal and lumbar regions.

Madame Mochnatcheff did a novel piece of research in that she made comparisons between blood obtained from the portio vaginals and the finger and found that there is a leucocytesis in pregnancy that blood from the portio contains fewer leucocytes than from the finger in pregnancy and that the reverse is true in labor

Payr stated that there is an adenoid character to the whole endometrium, and hence in labor the leucocytes are squeezed into the circulation, thus raising the count.

Rieder examined 31 pregnant women from fourteen to sixteen hours after eating and found a range of leucocytes from 10 200 to 16 500 with an average of 13 000. In 50 per cent in multipare: 18 cases) there was an increase among 13 primipare all but one showed an increase and during digestion in 6 cases there was a decrease.

Hosauer constructed curves from ao cases. The curve starts just above the nor mal goes up during and past labor dropping down soon after labor and reaches a level ten to twelve hours post partium which it main tains until the second to the third day of the purpernum, when there is a secondary rise associated with the incoming of the milk. Hosaided that the leucocytosis of pregnancy was due to the painless, rhythmical contractions that the first curve in labor was due to the work of the uterus, and the second curve to the activity of the breasts.

Wild examining 30 cases found an increase in the leucocytes in labor and explains the same by means of a comparison between the utenne surface and a wound surface. He states that the increase which continues into the puerperium is due to the resorption of the

Hibbard and White present the following conclusions (1) Leucocytosis exists in three fourths of all cases more often in primiparae in labor (2) In the puerperlum the curve drops first rapidly then slowly to normal, rising a little on the seventh day (3) Leucocytosis is greater in young women and less with each labor (4) Prolonged labor causes an increase. (5) Breast infections produce a rapid increase. (6) Leucocytosis of labor is an increase essentially in the polymorphonuclear neutrophiles.

Brégoune thinks there is an increase in the last of pregnancy which involves only the mpe forms of the leucocytes the young forms are decreased. The first day post partum there is a marked increase in all forms. In the puerperium the polymorphonuclear neutrophiles show a relative and absolute decrease. The eosinophiles are increased at the beginning of pregnancy decreased post partum and then increased steadily after the second day.

Namurini found that there is no increase in mulipars: The count stays within the physiological upper limit. There is a true leucocytosis of pregnancy in primipare There is an absence of leucocytosis of digestion. The count is actually less during digestion.

Carstanjen says the neutrophiles are m creased in pregnancy and decreased during the puerperlum. The lymphocytes are decreased in pregnancy and increased during the puerperlum. The large mononuclears are always decreased. The cosinophiles are decreased post partum and then on the seventh day of the puerperlum they are increased beyond the percentage found in pregnancy

C Hahl examined 36 normal cases in pregnancy labor and the puerperium. The least days of pregnancy. With labor there was a considerable increase due to the neutrophiles. Post-partum there was a gradual decrease reaching the normal in one to seven days. His comparisons showed with no contractions, no increase in leucocytosis with contractions, a marked leucocytosis. His explana tion was that the process is similar to the leucocytosis in infectious diseases poisons and malignant tumors all are due to the presence of an irritant chemotactic in nature in the blood. For comparison he noted the increase of leucocytes in the endometrium of pregnancy and in the muscular coat with a resultant increase in the blood stream. The increase in labor is due to mechanical com pression from the uterus. If the leucocytes die young there ha renewal of the supply from lymphatic sources due to the circulating irritant.

Zangemeister and Wagner examined 47 cases of healthy non pregnant nomen Thirty five showed a leucocytosis of over 10 000 and in one case 21 300 before the meal the majority of all pregnant women the leu cocytosis ranges from 7 500 to 15 000 authors found no difference between preg nancy and non pregnancy nor between primiparae and multiparae In 63 labor cases they found leucocytosis in nearly every case the maximum just post partum even triple the original count. The increase they decided was influenced solely by the progress of labor and not by the para age or consti They likewise considered it influ enced by the discharge of amniotic fluid the puerpenum they found a rapid decrease but a slight increase in the presence of severe after pains

Carton eliminated the digestion factor by taking counts at the same hour each day. In the minth month of pregnancy he found a range of eight to lifteen thousand with 70 to 80 per cent neutrophiles and a decrease in the cosmophiles. In labor the polymor phonuclear neutrophiles were increased, especially in primipare and there was an absence of cosmophiles. In the puerperium from the first to the third day, there was a decrease in the neutrophiles and an increase in the eosmophiles up to 3 5 per cent.

Birnbaum found that in the second half of pregnancy there was almost always a slight leucocytosis in primipare an average of 10 500 and seldom a leucocytosis in multip are:—average 8.480 He found a marked increase in labor especially among primip are with the maximum reached on the

Charto Prignan y to 4 weeks untepurtum (Michael Reese Huspital)

third day of the puerperium. He found that the increase in labor was plainly related to the contractions not related to the rupture of the membranes and he found the differential count unchanged in pregnancy. In labor he found the neutrophiles increased and the lymphocytes and cosmophiles increased

Blumenthal says the leucocytes showed a slight increase in pregnancy ranging from 3 400 to 11000 with a predominance of large mononuclear leucocytes. In labor the neutrophiles were increased the lymphocytes decreased and the cosinophiles and mast cells absent. In the puerperium a normal leucocyte count was attained in one day.

Given found a slight increase in pregnancy and a marked leucocytosis chiefly among the neutrophiles in labor and the puerpernum. He found no difference between the primipare and multipare and the increase was absent in cases of macerated fætus and the presence of anuma. Two to three weeks post partum there was a marked lymphocytosis proportional to the speed of convalescence.

Arneth's chief contribution was a special classification of the polymorphonuclear neutrophiles to which he ascribed a clinical significance. In the series presented here this classification was made but without meeting Arneth's expectations. In his classification the neutrophiles are divided according to the construction of the nucleus into five classes. The first class contains a single round celled nucleus the second two nuclei or nuclear parts elongated or round the third three nuclei or nuclear parts the fourth four and the fifth five or more.

Chart Leucocytosis in labor and puerpersum. (Michael Reses Hospital.)

In the last three classes there is a secondary division into round parts and loops. Arneth examined to pregnant women 5 primiparse and 5 multiparse. In the primiparse he found a count ranging from 7,800 to 11,000 in the multiparae from 3000 to 8600. found the neutrophile changes to be a displacement toward the left in other words, toward the first class of neutrophiles, or socalled young cells. The smaller the total count, the more the displacement toward the left and he found the neutrophiles to belong chiefly to classes two and three. In labor he examined six primiparae and two multiparae. All the total counts but one exceeded 10 000as high as 18 100 The displacement of the neutrophiles was still more to the left. In the puerperium there was a total decrease with the displacement back toward the right of the scale. On the third day post-partum

in the presence of lactation, no influence on the leucocytes was noted the count remain ing unchanged, and the neutrophiles remaining toward the left.

His explanation was that as in infections, there is a more rapid destruction of the leu cocytes, resulting in an increase in the total and an increase in the young forms that is classes two and three but the destruction is not so severe as to cause the appearance of chiefly class one cells.

Hans A. Dietrich laid special emphase on the fact that he used the Turck counter and the May-Gruenwald stain for differentiations. He analyzed to cases, carrying the same women through pregnancy labor and the puer perium, examining them every two weeks ante-partum, and he made analyses of the labor counts at various stages such as the rupture of the membranes, the beginning of

Chat Effect of multiparity

(M. hael Reese Huspital.)

pains the height of pains the birth of the head and daily post partum counts for eight All of this was done under identical external conditions the patients being in the and all examinations being made three hours after the meal time maintained that there can be no fixed nor mal maximum in pregnancy such as the arbitrary figure of 10 000 Each individual has her own normal count Hence he deter mined to state his figures in terms of increase or decrease in the individual case based on the low counts of pregnancy On this basis he determined that at the end of pregnancy there is an increase over the normal in pri miparæ of 3 o68 and in multiparæ of 1 234 The increase is in the neutrophiles cosmophiles were decreased in 17 out of the 20 cases and there were no appreciable changes in the lymphocytes In labor among primipare there was an increase of 8 506 over the normal and in multiparæ of 0.453 a maximum count of 34 200 - an increase of 18 500 and a minimum count of 16 400 - an increase of 2600. The maximum point is reached just post partum The contrac tions seem to increase the count. On differ ential examination it proved to be purely a polymorphonuclear neutrophile increase 13 normal cases post partum there was a rapid fall reaching normal on the third day The cosmophiles absent in labor reappeared on the first day of the puerpenum and then

became more numerous than during the nor mal pregnancy. There was no relation to lactation or after pains that he could deter

Dietrich offered as an explanation of the leucox tosis a comparison to the theory of eclampsia on the basis of toxins from the fætus and placenta. These toxins in normal cases call forth as neutralizers the neutrophiles especially. Therefore primipate have a greater number and multiparæ have a certain immunity. Uterine contractions throw more toxins into the circulation hence more neutrophiles appear from the bone marrow.

Possibly the work theory of Schultz offered by Hofbauer namely that increase in intra abdominal pressure results in a compression of the veins and an increase in the circulation time hence an increase in the leucocytes in the peripheral parts—in other words an apparent leucocytosis may be a part of the explanation

S Adach studied the blood changes in pregnancy and labor. He pointed out that variations in healthy non pregnant women are marked. The figures given by various observers are. Moleschott 12 605 to 14 000 Mallassez. 6 923 to 7 692. Duperte. 4 000 to 4 545 and Senator. 3 000 to 6 000. If there be such variations in the normal non pregnant counts the variations in the pregnant woman or in any unusual condition would

Chart s. Effect of duration of labor (Michael Rome Housetal)

therefore be proportionately greater considered as important factors the appara tus and technique condition of the subject, and the external factors. For apparatus, he used the Thoma-Zelss counting chamber but preferably the Turck. Hemorrhage, fever meal digestion exertion, were factors to be considered in the condition of the patient. Room temperature was a factor in that cooling seemed to increase the leucocytes, and vice versa. Adachi counted ten non-pregnant cases, in whom he found an average of 5 500 to 8,400 10 mine months pregnancies, in whom with the Thoma he found 6,800 to 12 600 and with the Turck, 4 960 to 10 520 and 14 cases in active labor from one half to five hours antepartum usually the second stage, in whom he found a range of 11,000 to 25 600 - in one case a 9,800 count. He found no increase in the ninth month of pregnancy over the non-pregnant state in this agreeing with Zangemeister and Wagner He found marked increase in labor proportional to the sevents of the contractions. He counted 98 cases in all, omitting 30 for various causes making his total in all groups 68 cases. How ever he saw almost all his cases only once or

at most twice His explanations are that in the ninth month of pregnancy there is no change in the leucocytes, erythrocytes or hamoglobin that in labor the leucocytes are increased proportionally to the contractions and he found no difference between primipare and multiparue all of which conclusions are at variance with the findings of most other reliable observers.

W Steben analyzed to cases in labor and the puerperium. He was unable to make comparative counts on the same women through pregnancy labor and the puerperium. He found an increase in the ninth month of pregnancy and approved strongly of Diet rich a method of following the individual case through her pregnancy labor and puer perlum, rather than the Adachi method of numerous totals from all possible sources. In labor he found a leucocytosis maximum of 21 000, minimum of 11 000 average of 17,000 with a constant decrease in the puer perium of all cases but two reaching the nor mal at the end of the second week. His differential analysis showed the neutrophiles to decrease throughout the puerperium, and determine the general curve. The lymphocytes increased a little on the first or third day possibly in relation to infection The cosmophiles were present in 50 per cent of the cases just post partum in which Sieben differs from most other authors who have found them absent - an increase throughout the puer perium or reaching a maximum on the third The neutrophiles and the lymphocytes were found to be reciprocal the one increas ing as the other decreased In the mononu clear lymphocytes the transitional cells and mast cells no rule applies His conclusions were (1) In labor there is an increase aver aging 17 000 (2) There is a return to the normal in the second week (3) In the dit ferential analysis the polymorphonuclear neu trophiles decrease steadily throughout the puerperium The lymphocytes polynuclears decrease but may use in a week to a figure greater than the labor total change occurs chiefly in the small lymphocytes. As the small lymphocytes increase the large lymphocytes decrease The eosinophiles were present in 50 per cent post parturn and their curve was parallel to that of the neutrophiles

No single worker analyzed a sufficiently large sories to establish a standard scale and the discrepancies between various investigators together with the varying conditions under which their results were attained made it seem impracticable to combine their figures even from only the more recent sources.

In this investigation single counts and differential analyses were made in 25 pregnant women (11 primiparæ and 14 multiparæ) one to four weeks before delivery and counts were made in a consecutive series of 100 ward cases in labor afterwards eliminating 15 because of fever (11 with one temperature of 100 2 or over and 2 with fever of several days duration) In each of these women a leucocyte count was made during active la bor and once daily thereafter for ten consecutive days Whenever possible the blood was taken in late forenoon late afternoon or at night i.e. when well removed from meal At the same time spreads were pre pared for differential counts and the poly morphonuclear neutrophiles were subjected to the Arneth analysis in an attempt to confirm his findings.

Chart 4 Effect f ppearance of milk (Michael Reese Hospital)

In the last month of pregnancy the average count in eleven primipare showed 10 900 or 2 900 above the mean normal of 8 000 (if we accept the normal range as 6000-10 000). The multipare (14 cases average 8 886) showed no change and the differential counts come very close to normal figures (Chart O)

Very early it was found that there is a striking difference between primipars and multipars a point little emphasized in the hiterature. In this series it is very noticeable (Chart 1). Among 30 primipars the average labor leucocytosis was 18 255 and the average high point 19 883 was reached on the first day of the puerperium with a steady tapering off from that to the tenth day 10 840.

Among 57 multiparæ (II para to VII para) the labor figure was 13 467 and the average high point, 15 662 again was reached on the first day of the puerperium then tapering to 10 467 on the tenth day

With each successive childbirth there seems to be a decreased reaction on the part of the leucocytes a kind of immunity if you please and in this respect the single XII para was striking (Chart II)

The duration of labor proved less of a factor than had been anticipated a noticeable increase beyond the average leucocytosis

Chart 5. Effect of age. (Michael Reese Hospital.)

occurring only in the primipare in labor over twenty four hours (Chart 3)

The incoming of the milk seemed not to affect the leucocytoss, except possibly in the group of fourth day primipare in which a secondary rise occurred on the third day and the single fifth day primipara, who reached her maximum count on third day (Chart 4)

Case grouped on the basis of age, each group covering a five year period showed the most marked elevation in the leucocyte count among the eight primipairs aged 18 to 20 Among the multipairs there was nothing noteworthy except the group aged 36 to 40 seven in number in which there was the least reaction, explainable, however on the basis of multiparity rather than age (Chart 5)

The differential analyses are in accord with the findings of the more recent workers notably Dietrich and Sieben The leucocytosis is of the polymorphonuclear type these elements reaching their maximum at the end of labor and on the first day post partum, the rapidly and steadily decreasing reaching normal proportions after five days in printing and three days in multipare. The cosinophiles were absent in half the labor cases, reappeared in normal proportions on

the first day post-partum and at no time were noticeably increased.

The small lymphocytes were diminished as the polymorphonuclear leucocytes in creased and the large mononuclear transition al forms and mast cells maintained normal percentages (Chart 6)

Classification of the polymorphonuclear leu cocytes on the Arneth plan was carried out systematically and showed the displacement toward the left, ie classes 2 and 3 of which he speaks but this was not a constant find ing

SUMMARY

There is a leucocytoms of pregnancy appearing in the ninth month slight in amount, and especially noticeable in primiparm

The leucocytosis of labor is marked in primiparie averaging 18 255 and is increased by a duration of labor beyond twenty four hours. It is less marked in II paree and is slight in III plus parie.

The hight of the curve in primipare and multipare is reached on the first day of the puerperium, after which there is a rapid and constant decline to the tenth day at which time the curve is about at the normal level

Chart 6 Differential analyses in per cent. (Michael Reese Hospital.)

The onset of lactation does not influence the leucocyte count except that in the fourth day primipara there is a slight secondary elevation on the preceding day — about 1 $_{5}\infty$ to 2 $_{5}\infty$

Age is not a factor except in primipare aged 20 years and under in whom the leucocytosis is higher than in any other group

Differential analysis showed the increase in leucocytes to be chiefly in the polumorphonuclear neutrophiles with a return to normal proportions by the third day of the puerperium an absence of cosinophiles in about half the cases in labor and their reappearance in normal proportions on the first day of the puerperium. The lymphocytes large and small mast cells and transitional types show ed nothing unusual.

The Arneth analysis showed a displace ment toward the lcft 1e toward classes 2 and 3 but this was not constant and no per tinent deductions could be drawn

To my chief Dr Lester E Frankenthal I wish to express my deep appreciation of the privileges afforded me in the Michael Reese

Maternity Wards and for his helpful sug gestions and invaluable criticisms in the carrying out of this work

PERITHELIOMA AND ENDOTHELIOMA OF THE UTERUS'

By W. A. NEWMAN DORLAND A.M. M.D. F.A.C.S., Carcacoo Professor of Oyucchegy Fox-Ocadesta Merical School of Cartago, F. et Londonson, Merical Reserva Carps, U. S. Army

A CASE OF PERITHPLIONA OF THE UTERUS

N October 1907 a tumor of unusual
scientific interest fell into my hands.
The clinical and pathological findings
were these (33)

The patient a fragil, singl woman, 63 years of age had been complaint of pagin in the pel vic region for littl over two months. Sh had writted w man physician f considerable ability who had made vaginal examination and had pronounced the condition betwentiation of the pelvis. The patient was placed on a suit ble course of treatment but without any amelikaratio of the symptoms. On the contrary the pain grew more severe and the patient was referred to me severe and the patient was referred to me.

I found the woman anamic and thin almost to gauntness. Her akin was shriveled and on the abdominal surf ce could be pi ched p in thin folds. It was sallow or pal yellowish in color After considerable difficulty due to the extreme modesty of the patient I succeeded in making vaginal exploration when the f ll w ing points were elicited. The vagins was small and ndergoing senile changes. The vulvar mucosa showed the characteristic smooth, yell w pretrance of sentility. The terms lay anteriorly was small although larger than would be expected from the ag of the patient and was distinctly sensitive to the touch. There was very slight discharge from the os sanguineous, b t without odo or ny decided appearance of hemorrhag At no time had th patient suffered from bleeding nor had she at any time noticed any odor t the small mou t of leucorrhea of which she complained. The history of the patient her age the conditi of anemia, and the local signs impressed on me the importance of making microscopic examination of the intra nterine curettings, and aft r considerable opposition this was finally agreed t Under ether anesthesia the uterus was scraped at the patient's home and considerable quantity of debris obtained. The examination at this time confirmed the findings of the previous explorate n, and also demonstrated th absol to m billty of the uterus and the healthy condition of the ovaries and t bes. The scrapings were sent to the distinguished pathologist, D O I K Ily since deceased wh eported that they showed an unusual condition of great malignancy which warranted the immediate removal of th uterus. He t this time pronounced th growth a perithelial sarcoma, the small tumor-cells showing an unusual degree of grouping around the vessel

Obrai as Two days later notwithstanding the general unfavorable condition of the patient, I removed the uterus and tubes, performing a parhyserectomy. This, at th urgent insistence of the patient was done ther home. I was ably assisted by Drs. H. A. Socum, G. A. K. owles, and F. A. Fa ght and to akilled rates. The operation was imple and neomplicated taking not more than thirty manutes for ta complet in. The patient made an unit terrupted recovery for three days. Then symptoms. I bowel-obstruct n supervened, and despite the use of earth and the other renedies and measures generally employed in this condition the patient and straidly and died of adaptine flews on the evening of the fifth day. Lawag, was not resorted to on account of the age and feeble or

dition of the patient. Pathologic part Dr Kelly report of the nothologi examination of the specimen follows scrapings consist of a new-gr with made up of a framework of fibrous connective tissue supporting large cylindrical cells, with clear vericular nuclei. The connective-ussue stroma is quite scanty and in som places altogether wanting. The tumor-cells. for the most part, are arranged radially about and attached directly t capillary blood vessels-whence morphologically the term peritbelial sarcoma seems justified. In other places there is diffuse infiltration of the tissue-endometrium and musculature by the tumor-cells. The uterus is rather small and reveals at the fundus rough excreacence about centimeters in diameter projecting into the cavity and infiltrating the wall of the uterus t a depth of seven to ten millimeters. Microscopically the growth consist of a connective-tissue stroma enclosing epithelial cells tranged after the manner of the glands of the endometrium. In general this glandula arrangement is more or less well preserved, but in many places it is altogether want ing and the epathelial cells infiltrate the tissues ir regularly as is common ; this type of tumor

This case is established therefore as one of the earliest recorded instances of perithell oma of the uterus one of the rarer group of endothelish tumors.

THE ENDOTHELIUM AND THE PERITHELIUM

In order to comprehend the difference and yet the very intimate relationship existing between the two groups of endothelial tumors about to be analyzed it becomes imperative to appredate the exact anatomical variation between the structures known as the endothe lium and the perithelium

It was His (,o) who invented the term endothelium for the flat cells composing the inner lining of serous cavities as well as of the blood vessels and the lymph vessels These cells have a definite origin from the mesen chyma - a layer of the primitive mesoblastas Courtauld (2,) established by his investi gations of the newly forming blood-capillaries in very early placental trisue. Courtauld proved conclusively that the endothelial cells originate in the loose connective tissue of the chorionic villi and that the epiblastic layers have no share whatever in the process It is obligatory therefore that neoplasms originating from these cells must be grouped with the mesoblastic growths side by side with the sarcomata whatever their histolog ical appearances may be. They must be sharply differentiated from the carcinomata notwithstanding their many points of resem blance to that group of tumors Because of their phylogenesis Lazarus Barlow (97) re marks that such tumors must be expected to show as they do a great variability of appearance ranging between that presented by a typical spheroidal cell carcinoma on the one hand and a typical sarcoma on the other While both sarcoma and endothelioma there fore have their origin in the mesenchyma it is probable that the sarcomata arise at an earlier and more primitive stage of mesen chymal development as is proved by their earlier clinical appearance that is in children and patients of tenderer years In describing the endothelium Lazarus

Barlow (96) states that normal endothelial cells are regularly arranged are flattened and round with a large round or oval nucleus and with a large amount of protoplasm to the cell. As a rule, the chromatin is collected round the periphers of the nucleus and also in the center while strands of chromatin extend between the two. Hince in section the nucleus is remarkable by its clearness and its appearance of vacuolation. Mallors (112) adds that the endothelial cell is characterized by no production of fibrils hence it stands out in marked contrast to the neuroglia cell. These endothelial cells are found in

special regions notably in the blood vessels the lymphatics and the lymph spaces

The perithelium on the other hand is the layer of endothelial cells which surrounds the capillaries and smaller blood vessels, that is the external boundary or adventitia of the vessels running through the perivascular spaces but not the cells forming the external wall of these spaces Eberth and Iwanoff (35) in 1870 fir t described the perithelium in the vessel of the pia mater and demonstrated them by staining with silver nitrate. Zeit (198) who in the country has probably most thoroughly studied these tissues emphasizes the fact that the penthelial membrane must be differentiated from the perwascular lymph spaces of His (70) which that anatomist described as surrounding the adventitia of arteries veins and capillaries of the central nervous system (which has no lymph vessels) The perithelium Zeit repeats is the outer liming of the adventitia of blood vessels, out side of which is the penyascular lymph In 1871 von Ebner (36) described space the purithelium in the vessels of the pineal gland the suprarenal capsules the thymus gland and the salivary glands Waldever (102) and Sertoli (166) in 1868 described it in the vessels of the coccygeal gland and Palt auf (127) in 180 reported its presence in the carotid gland

THE HISTOLOGIC FEATURES OF PERITHELIOMA AND ENDOTHELIOMA

As is true of all other tissues it is possible for neoplasms to develop from these delicate membranes Stolz (1,6) calls attention to the fact that Golgi as early as 1860 first spoke of an endothelioma as a growth originating from endothelial cells while Kolaczek (84) in 1878 made the first great analytical study of endothelial tumors and recognized the condition as belonging to the group of angio sarcomata Marchand (113) and Weichsel baum in 1870 carried on these investigations both regarding the endotheliomata as tumors sus ecneris Maurer (116) in 180 the name perithelioma to th endothelial tumors arising from the adventitia of the blood vessels Finally Ribbert (149) 1001 stated that the endothelial tumor arising from the blood vessels is a very rare growth—much more so than that ansang from the lymph-channels and this observation is verified by the summary of all recorded endothelial tumors accompanying this

It is unfortunate that there has been some confusion in the employment of these terms. The following resume may aid in elucidating the matter Under morbid stimulation endothehal cells wherever found will prohierate and this prohieration may take place inward ly or outwardly or in both directions at the same time. In the words of Lazarus Barlow (o6) who with Bayon (11) the English pathologist has given this subject exhaustive Outward proliferation will lead to the production of a central space lined with endothehal cells, and surrounded by two three or many layers of cells, more or less regularly arranged, and with characteristic Such a growth springing from the adventitia of a blood vessel is designated a The important point to note berithelioma. morphologically is the persistence of the central lumen Lazarus-Barlow believes that this characteristic feature is doubtless due to the greater rapidity with which the blood flows through the capillaries together with the high hemal tension both of which militate against cellular probleration inward. His conclusion that because of these physical peculiarities enthellomatous growth should be more common in the case of lymphatics and peritheliomatous growth in the case of blood vessels is verified chnically and by the histological findings of all recorded endothelial tumors. It must be admitted however that it is difficult in some cases to definitely conclude where the growths originated, although the presence of red blood-corpuscles in the lumina of peritheliomata will usually deter mine their origin from the blood vessels.

If adds Lazarus-Barkow the growth shows hundra containing a fairly curumsribed mass of albumin which has undergone coagulation in the process of fixation and has given rise to hirlin and a certain amount of granular dCbris the growth has probably originated in a lymphatic.

If on the other hand, the proliferation of

the endothelial cells takes place inwardly the central space lined with endothelial cell. will become choked with a mass of cells. Such a growth 1 known as an endothelioma According to these two hypothetical meth ods of growth continues this pathologist it should be possible to divide the endothell omata into the peritheliomata and the entheli Further if the perithelioma process occurs in different situations but in close contiguity the effect will be that of a number of spaces each more r less closely resembling the original space but separated from one another by a mass of cells produced by the outward proliferation and coalescence of the endothelial lining ()n the other hand, in a growth of the endothelioma type a number of cell masses will be seen corresponding to normal lymphatic spaces in which the lumina have been distended and filled with cells and which are separated by ordinary connec tive tissue A combination of the two processes may occur leading to a type of growth that may fairly be called a perienthelioma To this distinction Bayon (11) adds that

all growths presenting a radial disposition of cells around blood vessels the endothe lial lining of which is intact may be termed pertikelionala even if it cannot be conclusively shown that they originate from the perthelium, that is from the endothelial cells covering the adventitia of the blood vessels.

HISTOLOGIC CONCLUSIONS CONCERNING EN

As a primary corollary then it may be stated that both endotheliomata and per theliomata are in reality endothelial tu mors that is taking their origin in endothelial cells and secondly that they are more remotely still very closely allied to if not constituting a true variety of succomata. More over from a morphologic standpoint, it is evident, from the foregoing analysis that it is evident, from the foregoing analysis that it is evident, from the designate only a peculiar class of the growths springing from the delicate external layer of cells around the minute blood vessels and showing the characteristic radial disposition of the tumor-cells which

according to von Hansemann (60) is due to the growth cells being more readily nounshed in that position. The characteristic cellular proliferation begins at the external wall of the vessel and not in its lumen a in imple hemangio-endothelioma but they are not as Barbour (10) claims in reality endothelio mata derived from the lymphatic (198) emphasizes this distinction when he remarks it is wrong to speak of a peri thelioma as arising from a lymph vessel because perithelial membranes cover the outer surface of the adventitia of blood vessels only in a one-cell layered mosaic of flat en dothelium like cells. They have only been found with blood vessels of certain organs called penthelial organs. A penthelioma cannot therefore be spoken of as arising from lymph vessels nor from blood-capillaries The term berithelioma is confined to certain tumors of the blood vessels of perithelial organs only Yet so-called perithelial tumor or angiosarcomata do occur in non perithe hal organs which are morphologically similar to the true peritheliomata. From a histogenetic point of view it is desirable that the term be reserved for a class of tumors arising from perithelium only

With the reservation Zeit concludes order then to armye at a histogenetic classification of these tumors we would have to be able to distinguish whether the proliferation of cells had their origin in the true perithelium of blood vessels which lines the outer surface of the adventitia in perithelial organs (perithelioma) in the inner or both endothelial layers of a perivascular lymph space or in the adventitia cells or penvascular cells of blood capillaries Pick (134) and Rosthorn (155) call all these endothelium like layers perithelium and their proliferation a perithe lioma Borst (10) also wants to use the name perithelioma for all these tumors with the understanding that it is a kind of offspring of endothelioma. In case one is able to prove that the growth originated from the endothe hum of the perivascular lymph spaces it should be called endothelioma perivasculare (Borrmann's (18) periendothelioma) Borr mann thinks he can distingui h morphologi cally between the two types as follows peri

thelioma when the vessels are surrounded by many layers of cells which are arranged [with their long axes] radially and ver tically to the wall of the vessel periendotheli oma when the vessel are surrounded by many layer of cells which are arranged con centrically around the wall of the vessel Zert differs with this view and prefers to use the name hæmangio-endothelioma peri ascu lare for the so-called perithelial or peri vascular tumors. On the other hand the hæmangio endothelioma intravasculare of Zeit originates only from blood-capillaries and has been called by Ziegler hæmangioma hypertrophicum by Nawerck hyperplastic capillary angioma and by Borrmann capil lary endothelioma These tumor consist of a stroma of fibrous tissue with gland like tubes tilled with blood and fined with one layer of endothelial cells which may be cubi cal or cylindrical in shape

THE CLINICAL ANALYSIS OF ENDOTHELIAL TUMORS

With this hasty summary of the histological distinctions between the two groups of endothehal neoplasms it is interesting to proceed to an analytical study of the clinical peculiarities of these tumors with special reference to their occurrence in the finale generative organs. An exhaustive investigation of endothehal tumors was made by Rudolph Volkmann (190) in 1895 and more recently by Max Borst (20) in 1902 while Zeitschmann (00) has presented an exceedingly interesting treatise covering the recorded information up to 1904 concerning perithelioma as occurring in lower animals.

At the most not more than 300 end) thehal tumors of all Linds have been recorded to date in the various portions of the human body. It must be conceded therefore that they are among the rarest of neoplasms although it is probable as Roussy and Ameuille (156) have claimed that they are commoner than would appear and that many cases were formerly described as angiovarcoma and angiovarcoma pleuforme.

Any part of the body may be attacked by the growth The commonest sites of surgical interest according to Carless (6) ap ing from the blood vessels is a very rare growth—much more so than that arsing from the lymph-channels, and this observation is verified by the summary of all recorded endothelial tumors accompanying this bases.

It is unfortunate that there has been some confusion in the employment of these terms. The following résumé may aid in elucidating the matter Under morbid stimulation endothelial cells wherever found will problemate and this proliferation may take place inward ly or outwardly or in both directions at the same time. In the words of Lazarus Barlow (o6) who with Bayon (11) the English pathologist, has given this subject exhaustive Outward proliferation will lead to the production of a central space lined with endothelial cells, and surrounded by two three or many layers of cells more or less regularly arranged and with characteristic nuclei. Such a growth springing from the adventitia of a blood vessel is designated a The important point to note bersikelsoma morphologically is the persistence of the central himen Lazarus-Barlow believes that this characteristic feature is doubtless due to the greater rapidity with which the blood flows through the capillaries together with the high hemal tension, both of which militate against cellular proliferation inward conclusion that because of these physical peculiarities entheliomatous growth should he more common in the case of lymphatics and perithellomatous growth in the case of blood vessels is verified clinically and by the histological findings of all recorded endothelial tumors. It must be admitted however that it is difficult in some cases to definitely con clude where the growths originated although the presence of red blood-corpuscles in the luming of peritheliomata will usually deter mine their origin from the blood vessels. adds Lazarus-Barlow the growth

If adds Lazaria-barlow the glown shows lumina containing faulty circumscribed mass of albumin which has undergone coagulation in the process of fination and has given rise to ibina and a certain amount of granular debris, the growth has probably onstanted in a lymphatic.

If on the other hand the proliferation of

the in lothelial cell takes place inwardly the central space lined with endothellal cells will become choked with a mass of cells. Such a growth 1 known as an endothelloma

According to these two hypothetical meth ods of growth a number this pathologist it should be possible to divide the endotheli omata into the peritheliomata and the entheli Further if the perithelioma process occurs in differ nt situations, but in close contiguity the effect will be that of a number of spaces each more or less closely resembling the original state but separated from one another by a ma- of cells produced by the outward problemate n and coalescence of the endothelial lining. On the other hand in a growth of the endothelioma type a number of cell masses will be seen corresponding to normal lymphatic spaces in which the lumina have been di tended and filled with cells and which are separated by ordinary connec tive tissue A ombination of the two processes may octur leading to a type of growth that may fairly be called a perienthelioma To this distinction Bayon (11) adds that all growths presenting a radial disposition of cells around blood vessels the endothe hal lining of which is intact, may be termed peritheliomata even if it cannot be conclusively shown that they originate from the perithelium that is, from the endothelial cells covering the adventitia of the blood vessels

HISTOLOGIC CONCLUSIONS CONCERNING EN DOTHELIAL TUMORS

As a primary corollary then it may be stated that both endotheliomata and peri theliomata are in reality endothelial tumors, that is taking their origin in endothelial cells and secondly that they are more remotely still very closely allted to if not constituting a true variety of sarcomatin More over from a morphologic standpoint, it is evident, from the foregoing analysis, that it is evident, from the foregoing analysis, that it is evident from the toregoing analysis, that it is of the growths springing from the delicate external layer of cells around the minute blood vessels and showing the characteristic radial disposition of the tumor-cells which

according to von Hansemann (60) is due to the growth-cells being more readily nourished in that position. The characteristic cellular proliferation begins at the external wall of the vessel and not in its lumen a in simple harmangio-endothchoma but they are not as Barbour (10) claims in reality endothelio mata derived from the lymphatic (108) emphasizes this distinction when he remarks it is wrong to peak of a peri thelioma as arising from a lymph vessel because perithelial membranes cover the outer surface of the adventitia of blood vessels only in a one cell layered musaic of flat endothelium like cells. They have only been found with blood vessels of certain organs called penthelial organs A perithelioma cannot therefore be spoken of as an ing from lymph vessels nor from blood capillanes The term perithelioma is confined to certain tumors of the blood vessels of perithelial organs only Yet so-called perithelial tumors or angiosarcomata do occur in non perithe hal organs which are morphologically similar to the true peritheliomata. From a histogenetic point of view it is desirable that the term be reserved for a class of tumors arising from perithelium only

With this reservation Zeit concludes Ĭη order then to arrive at a histogenetic classitication of these tumors we would have to be able to distinguish whether the prolifera tion of cells had their origin in the true pen thelium of blood vessels which lines the outer surface of the adventitia in perithelial organs (perithelioma) in the inner or both endothelial layers of a perivascular lymph space or in the adventitia cells or perivascular cells of blood capillaries Pick (134) and Rosthorn (155) call all these endothelium like layers perithelium and their proliferation a perithe Borst (10) also wants to use the name penthelioma for all these tumors with the understanding that it is a kind of offspring of endothelioma In case one is able to prove that the growth originated from the endothe hum of the perivascular lymph spaces at should be called endothelioma perivasculare (Borrmann's (18) periendothelioma) mann thinks he can distinguish morphologi cally between the two types as follows peri

theliama when the vessels are surrounded by many layers of cells which are arranged [with their long axes] radially and ver tically to the wall of the vessel periendotheli oma when the vessels are surrounded by many layers of cells which are arranged con centrically around the wall of the vessel Zeit differ with this view and prufers to use the name hamangio-endothelioma permascu lare for the so-called perithelial or pen On the other hand the vascular tumor hæmanero endothelroma intra asculare of Zeit originates only from blood capillaries has been called by Ziegler hamangioma hypertrophicum by Sawerck hyperplastic capillary angioma and by Borrmann capil lary endothelionia. These tumors consi t of a stroma of fibrous tissue with gland like tubes tilled with blood and lined with one layer of endothelial cells which may be cubi cal or cylindrical in shape

THE CLINICAL ANALYSIS OF ENDOTHELIAL TUMORS

With this hasty summary of the histological distinctions between the two groups of endothelial neoplasms it is interesting to proceed to an analytical study of the clinical peculiarities of these tumors with special reference to their occurrence in the female generative organs. An exhaustive investigation of endothelial tumors was made by Rudolph Yolkmann (190) in 1895 and more recently by Max Borst (20) in 1902 while Zeitschmann (200) has presented an exceedingly interesting treatise covering the recorded information up to 1904 concerning pt. 1 thelioma as occurring in lower animals.

At the most not more than 300 end) thehal tumors of all kinds have been record ed to date in the various portions of the human body. It must be conceded therefore that they are among the rarest of neoplasms although it is probable as Rous y and Ameuille (156) have claimed that they are commoner than would appear and that many cases were formerly described as angiosarcoma and angiosarcoma plenforme

Any part of the body may be attacked by the growth. The commonest sites of surgical interest according to Carless (26) appear to be the skin testes, throat, the parotid and submaxillary glands, the neighborhood of the mouth and cheeks the long bones, and the carotid gland. Other regions in which au thentic cases have been noted are the eye lid the optic nerve the soft palate the pelvic connective tissue the brain the subcutaneous connective tissue, the muscles the kidney the mamma, and certain serous membranes as the pleurs. Wherever occurring these tumors show a marked tendency to undergo hyaline degeneration.

In their relation to sex. Carless states that endothelial tumors are slightly more common in women than in men Karsner (77) endorses this statement discussed a formation of the cases occur before the age per cent of the cases occur before the age of 40 and 73 87 per cent after that age Karsner claims that the disease appears particularly in the fourth fifth and sixth decades of life that is between 31 and 60 years

of age About one-third of all the recorded cases have occurred in the female generative or gans. Thus Lange (94) up to 1903 col lected over 40 cases of endothelioma of the ovary Since then additional cases in the overs have been reported by Godart (54) Lincoln (106) Schuermann (163) Federlin Papalannou (128) Heinricius (65) Procopio (141) Kubo (92) Carl (25) Eymer (10) and Ligabue (101) Perithelioma of the ovary is much rarer but fifteen cases in all having been recorded by Steinhaus (175) Burckhard (24) Krukenberg (90) Menetrier (117) Graefe (56) Pollak (130) Mirabeau (121) Goth (55) Uffreduzi (184) Neumann (125) Amann (5) Bender and Proust (14) and Barbour and Watson (10) Karsner (77) records a case of primary endothehoma of the omentum Schmidlechner (162) a case of perithelioma of the labia majora, and Bar bour and Watson (10) a case of perithelioma of the fallopian tube

ENDOTHELIAL TUMORS OF THE UTERUS FROM THE CLINICAL POINT OF VIEW

Macnaughton Jones (109) correctly re marks that it is only within recent years that uterine endothelial tumors have been de

scribed. Comparatively few of these cases are on record and this is especially true of perithelioma but, as Watson (103) has re marked the condition cannot be so rare as the small number of cases indicates. Many of them have been described as sarcomata and many others occurring as secondary changes in fibroids have not been recognized at all In a large percentage of the cases the tumor has arisen in a pre-existing fibroid, or has itself formed a large tumor in the uterine wall which has been mistaken for a fibroid. A few of the cases as Watson's and my own were unassociated with perceptible tumor formation having apparently originated in the corporeal mucosa. Now that the existence of these tumors is becoming more gen erally recognized as well as their intimate association with a pre-existing fibroid change in the uterus, it is very probable that a progressively larger number of endothelial tumors will be placed on record in surgical It is at least suggestive as hterature Lazarus-Barlow (o6) states that in the Mid diesex Hospital in London where a careful pathological examination of every tumor is made during the period from 1900 to 1904 endothelioma constituted to per cent of the

mallement tumors of the uterus I have been able to gather from the litera ture just 50 cases of endothelial new forms tions in the uterus of which 18 were of the peritheliomatous type and 32 endothelioma tons. These are grouped in the tables which are appended with the exception of Svoboda's (177) case of endothelioma of the cervix and Szerszynski s (178) and Zembrzuski s (199) cases of perithelioma, the records of which were not accessible. It is interesting to note that two of these cases occurred in the work of members of this Society. It is to be regret ted that the clinical and pathological reports of some of these cases are very incomplete but even so a critical review of the cases elicits interesting and suggestive points. Thus the tables verify the claim already made that en dothelloma is much more frequent than pen thelloma - about in the proportion of 2 to 1

Age The average age of all the cases was 46 years. Perithelloma seems to develop a little later than endothelioma the cases averaging 4814 years while the average age of the endotheliomata was 4334 years

The social relations of the patients are not Seven of the women recorded in 11 cases were single and 20 were married with from none to nine children. One of the women was but 18 years of age another 19 and a third 27 the rest were 30 and older the oldest woman being 68 years of age the next oldest 65 a third 64 and two 62 years old teen of the women were 50 years old or more As two-thirds of the women with uterine sarcoma are below the average in child bearing have not reached puberty or have not borne children for a long time a striking chinical difference will here be noted between uterine sarcomata and endothelial tumors

Symptoms Bleeding at times amounting to flooding at times merely a slight show is a very persistent symptom only 5 of the cases giving no such history. At a later period in the course of the disease these women would probably have developed the symptom Generally the clinical manifestations are those of malignancy—bleeding fetid puru lent discharge and pain—or those of fibroid tumor—bleeding with a decided tumor mass or uterine enlargement. The cases give a death rate of 29,9 per cent, including the primary mortality—ity per cent—and death from later complications and recurrence.

Site of the tumor. Of the perithelomata but one originated in the cervix while of 31 endothelomata the location of which are noted 16 slightly over half sprang from the cervix—7 from the posterior lip 4 from the anterior lip and 5 from the cervix generally without special localization. But 2 endo thelomata developed in the fundus and right cornu while 1 were located in the corpus 2 involving the posterior wall and 10 the interior. Six of the perithelomata originated in the fundus and 10 in the body of the uterus. It would appear therefore that endotheli omata preterably develop from the cervix and portheliomata from the uterus isself.

THE ASSOCIATION OF ENDOTHELIAL TUMOR WITH OTHER NEOPLISMS OF THE UTERUS

Letth (QS) in the Ingleby Lectures for 1910 upon the pathology of tumor of the

corpus uters and Shaw (167) in 1913 both call attention to the frequency with which these endothelial growths in the uterus oc cur in association with or actually within the tissues of fibromyomata and especially when there has been no pre-operative sus picion of malignancy Shaw remarks that this may possibly account for the few cases recorded many doubtless being thrown away as fibromyomata without microscopic exam mation Of the tabulated cases 10 were as sociated with fibromata or fibromyomata while in 25 cases no such tumorous formation was noted \ll the fibroid tumors which had undergone the malignant degeneration were located in the body of the uterus thereby substantiating the claims of Montgomery Weir Williams and others that sarcoma of the body of the uterus is more common than sarcoma of the cervix

In 1860 C Mayer first described uterine

sarcoma his case being termed by him a sarcomatous polyp The occurrence of sar comatous change in fibromyomata was first clearly described by Virchow (187) in 1862 who pointed out the origin of these tumors from the connective tissue of the myoma 1867 G Veit first described sarcoma of the cervix Finally Geist (52) in 1913 while speaking of malignant changes in uterine fibroids with special reference to the histogenesis of sarcomatous change in these tumors The interstitual tissue of the myoma and the adventitia and endothelium of the lymph and blood vessels have been recognized and accepted as sites of origin of sar coma To these must be added the muscle cells proper [of a myoma] Leith (o8) adds suggestively We thus have a variety of sarcomatous growths arising within fibroids -the endothelioma the perithelioma the myosarcoma and the myoma sarcomatodes which may be the explanation of the relatively low degree of malignancy exhibited by most of these growths Those originating in fibro blasts though varying greatly in malignancy show it in greatest degree whilst the myo sarcoma is the least malignant of all the other two forms showing varying intermediate Bayon (11) confirms this view as degrees to the relatively low degree of malignancy of endothellal tumor stating that metastases are not at all frequent with these tumors which is diametrically opposed to the general expectation when there is taken into consideration the extreme vascularity of the tumors, their intimate approximation to the blood vessels, and their multiplicity of small cells. They are however he adds, characterized by infiltrative and rapid expansive growth but on complete and thorough operative procedure do not show a tendency to recur

CONCLUSIONS

The following deductions may be drawn from this pathological and clinical review

- 1 Endothelial tumors of the uterus develop late in life—much later than sercomata the peritheliomata generally occurring at the most advanced age.
- 2 These growths are especially prone to occur in a pre-existing neoplasm—a myoma or a fibromyoma
- 3 While showing a high degree of local malignancy they but rarely give rise to me tastatic deposits elsewhere
- 4. It is probable that endothelial uterine tumors occur more frequently than would appear. Hence the importance of early removal of all uterine growths which should always be subjected to a careful pathologic eramination.

th (andus) composed of hard tumor ik mass, of hite, scurbous presurance C t surface smooth white presurance with fine urregular and round mosale-lik fields. The mucosa a smooth trophic glistening Micress for hadings Section of the t me shows fibrille ground substance with solid cellular cords cut in long! tudinal and trans-erse sections. Lymph venels and lymph spaces lined th proliferating epithelloid cell-masses These cords of cells appear lik cellular cylinders of large diameter (lymph vessel endothelioma) or as delicat cellst ps of t layers of flat ell branching here and there (lymph space endothelioma) The larger endothelial cell masses have merous so-called lumina containing mucold material. Other portions of the tumor look lik scirrhous carcinoma. It is: lymphangio-endothelloma intravasculare of the terus Vaganal hysterectomy Death in is month from multipl metastatic tumors. CASE S Reported by F J M Weeney and M J Gabron J of Path & Ba tenol 907 m 3 Patient aged 5 Married nullipara CI real history Well until 48 then irregular terms hemorrhages. C retted, and polyp removed Hamorrhage shortly recurred. Uterus size of t months pregnancy er, hard sensi-tive Adneva normal Three months later curetted. Large succedent masses removed. Have w bic find g. Uterus 45 inches long 5 inches wide all uniformly thickened. Inner urface quit amooth. Embedded in wall t circumsenbed nodules size of harelinits, one lack above upper end of cerv the ther inch from fundus, both softer than surrounding tresue lower one greenah tint on section Muracopi and go Lower nodule converts of an intimat admireture of succoma th cancer large spindle cells mixed th rregularly shaped cells mant-cells some with umerous nuclei. The car commetous portion consuts of groups of large cells clear th large exicular model cells round square, nd cylindrical The groups in many places show central I mins, either empty or choked th debris of polynuclear leucocytes Some of the lumina urrounded with but single la er of cylindrical epithellum. Upper nodul composed of groups of large cells with or ithout lumina, they are embedded in dense fibromoscular atronia. The endotheilal cells lining the lymph-clefts in the terine wall bet cen the nodules are multiplied to produce row of large cells markedly hyperchromatic. Some profiferation of endothelium of the small blood-vensels. Combined sar consa and endothelioms of uterine all Hysterectomy CASE so Reported by M. H. Phillips, J. Obst. & Gynack Brit. Lmp. 908 xill, 3. Patient aged co. Married ullipara widow fifteen years. Cl most k ster For also years increasing menorrhegia severe h pogastric cramps for fourteen months interprenational harmon rhage I'or several months offensive lescorrhea. Back Loss of fiesh and strength Profuse purplent leocorbrea, containing necrotic material. Uterus are of four months' prepancy b t filled ith firm, rounded t mor the use of goll-ball underguing necrotic below. If accuse per finding: Uterus 14 centimeters long 134. If acressing the start of the s featured presenting accretic ranged surface t the uterms cavity Lower portion ovoid in shape; vellowish whit of firm consistence ith smooth, round surface. If cro-scopic field p. Tumor largely composed of irregular masses of cells lying bet cen the nuncular and abrous bundles. The cells remainly polyhedral in shape but there are also umerous rounded and spindle-shaped cells. All

ell-defined nuclei, moderately rich in chromatin, and

with nucleol The cell-masses are carcinomatous in type They are closely packed in irregular spaces which some times show a flattened endothelial lin ng In these ir regular paces (lymphat cs) there is no intercellular mate d'at places there is a dist et prollferation if the nal endothelial lin ng At places the cells are arranged in a concentric (ship round both large and small blood vessels. The tumor has arisen fr m nabnormal proliferat on of the endothelial fell lining the lymph paces many of which re filled with the tumer-cells. There a associated glandula carcunoma of the indometrium. Abd minal hysterect my Death f weeks late of phlegmann alba dolens and epite thrombos if left pulmonary artery

HÆMANGIOMA CAVERNOSUM

REPORT OF A CASE

BY WILLIAM E LOWER M.D. FACS CILVELIND ONIO

CLASSIFICATION AND ETIOLOGY

F one may judge from the literature published under the general head of haman ground there is considerable confusion concerning the real nature of this condition. In the reported cases for example there are several instances in which tumors classified as hemangiomata apparently were really either angiomata or nevi classifies as hæmangiomata those tumors consisting of arteries capillaries and veins which are supported and held together by connective tissue or by tissues homologous with it such as adipose and mucoid tissue In his differentiation of all hamangiomata into three groups simple arterial, and caver nosum he includes in the latter class those in which there are large vascular spaces or muses fined with endothelium. With its reticular blood spaces the hemangioma cavernosum is similar in structure to the corpus cavernosum of the penis The irregu lar paces are tilled with blood they com

rounded with a retiform librous tissue which also contains clastic fibers the network varying in thickness in different parts of the tumor. The mass is fed by a single artery and discharges its blood into the dilated years.

A hæmingioma cavernosum is evidently the result of some anomaly in development the exact nature of which is unknown Nicholls finds this growth in situations corresponding to the embryonic lines of fusion such as the facial or branchial clefts. Karmisson defines the usual positions of hemian gioma cavernosum as the anterior and lateral parts of the neck where it often extends along the whole of the neck from jaw to clavicle.

Ilig Case of hum gioma ca emosum h wilg roentgenogram of y t.

municate with each other and they are sur

Fig Case of harmangi ma ca erroum baby fou months old showing size ad location of the tumo

Fig. 3. Case of hermangions cavernousm, showing result after excision, sho the im of incision.

or it may be limited to one part as to the submaxillary or the supraclaviount fossa. It may extend from the very front to the back of the neck or from the base of the skull to the clavicle. In fact, cases are recorded in which the tumor has passed under the clavicle and has extended into the axilla, and others in which it has invaded the mediastinum after passing behind the sternium. Whatever its satuation this growth has a tendency to ad here closely to the sheath of the great vessels emecially to the fugular venn.

In Lexer Bevan it is stated that harman goma cavernous is partly expansive and partly infiltrating in character it may be slow and continuous in growth or it may increase rupidly after a stationary period Not infrequently an encapsulated harman gloma is found which has ceased to grow. In most cases, however the mass gradually infiltrates the neighboring tissues including both the cellular spaces and the muscles themselves. After thrombosis and cleatrical contraction of parts of the tumor the involution may be complete

DIAGNOSIS

The peculiar color and form of this variety of hæmangioma practically assures the diag

nosis. Another distinguishing characteristic is the fact that the cyst may be decreased by pressure immediately assuming its original size and form when the pressure is removed. The tumor is bluish in color and increases in size when the patient coughs or cries. It is encapsulated and palpable and since it is fed by a large artery it pulsates. Mortis thinks all cavernous hæmangiomata are present at birth though they often are not noticed immediately.

TREATMENT

The usual treatment of a hæmangioma cavernosum is its complete extirpation al though Carl Beck has devised an ingenious method by which the masses of yessels are gradually transformed into connective tissue by a subcutaneous spiral ligature. manner the circulation is shut off within This procedure is repeated the tumor until the tumor has been diminished to the smallest possible nodule of connective tissue and the healthy skin enlarged to the utmost. Then the hard connective masses are excised and the borders united in fine linear union It is necessary to ligate the largest afferent vessels

CLINICAL HISTORY OF CASE

The appearance and treatment of a typical case of hæmangioma cavernosum is well illustrated by the following history of a case of my own

The patient baby of four mo the, was referred to me by D. Schnoldt and on January 2, 0, was sent t. Lakeside Hospital. The father was living and well t 50 the patient being the only hild of a second marriage. The mother had history of kidney trouble and pein in the back, but no dyspine or welling of the feet. The f may history was negative for malezancy or heart disease.

The patient full-term baby was bottle fed, and had never been side. Soon site birth the mother noticed a small lump bout the size of a wain 1 just bowe th clavide: he right sid of the neck. This mass was quite soft and was the lor f the surrounding tissue. Palpation was the panful. The tumor gradually increased in size until the child was three months of age when it bearn to assume

blush tinge. Whenever the baby cried the mass ppeared t increase in size but there was no companying pain. At the time the case first came under my observation, the mass had reached the size of a

Hig 4 Case i harmangoma ca ernos m howing iz nd hape i mas after ex isi n.

large lem n and o upsed an area on the right ide of the neck extending from beneath the scapida and la i le almost up to the ear (Fig. 1. It was blut.h in olor and in reased in ize when the baby cried or was hid up by it teet. On palpation it was found to be soft to the and seemed multilocular in hara ter. Light did not pinetrate the mas. On ontinued gentle pressure it decreased slightly in size and some pain was fused. The skin was freely movable over the tumor with h was somewhat alherent to the underlying tisse in oil initie pedi lebeing discovered. The roenigenogram howed a seen lebnic outline of the tumor time?

Under nitrous oud and overen anxithesia an in bion was made around the base of the tumor with the idea that if omplete removal became too hazardous it might till be possible to ligate or com pr s the vessels upplying it. By harp dissection I was able to cut around the growth and finally to remove it intact. The cv t was in close proximity to the large vessels of the neck, extended behind and below the clavicle was in direct contact with the pleura its tip being behind the scapula. The blood supply apparently came from a branch of the sub-Hæmostasis was secured by nne clavian arrery ilk ligatures and the wound was closed with con tinuous utures of to 16 ill. The dressing were put on very loosel so as not to interfere by pressure with the inculation in the flap. There was an imm diate harp rise in temperature but the patient made a omplete and rapid recovery

The pathological examination confirmed our dispinous of brainingoma avernousin. The tumor wighed it grams and measured oxfort, centimeters (Fig. 4). It was coursely lobulated, reddish purple in color and flurtunit. The surface was overed by numerous small fat tabs. The mass was soft votte thin walled and was apparently divided into numerous small and large communiting cavities. The contents of the mass consisted of oxidations.

F t Case f hæmannism ernis m h secti nithrough all

ub: entimeters of thin brown h hoodstee olored duit and some old broken down bloodstoft. The inner lining was mooth glistening and membranou. In one of the smaller spil see there were present organizing blood lots adherent to the wall. The maller and larger pales were often onested by une ord like tru tures resemblin, chords ten dont. No very large or definite blood vessels were found entering or emerging from any of the paces.

A mi-ro-copi examination of a section through the wall (Fig 5) howed a fibrous tis he tramework in which were numerous tairly large thin walled endothelial lined paces filled with blood. Many of the vessels had well-defined coats while others were imple spa es lined with endothelium. There was onsiderable lymphocytic and eosinophili intiltration chiefly around these blood vessels. There was also onsiderable coarse browns, h pigment scattered about chiefly intracellular. The walls of the large pa es con isted of a thick fibrous inner coat lined by endothelium in pla es and of an outer muscular The histological appearan e was that of greatly distended veins having well defined fibrous and muscular coats. The lesion was omparable with evetic hygroma, the blood vessels instead of the lymphatic system being involved in this ase diagnosis of the pathologist was congenital blood cvst or cavernous hæmangioma

AN OPERATION FOR THE RELIEF OF EPISPADIAS IN THE MALE:

BY I DELLINGER BARNEY M.D. F.A.C.S. BOSTON

N view of the well known difficulties en countered in dealing with epispadias in the male. I wish to describe an operation for its relief which we have found to be simple and efficient.

There are certain definite indications for operation (1) to relieve urinary incontinence (2) to change the point of exit and the direction of the urinary stream and of the semen (3) to change the direction and length of the penis (4) to restore the penis to a more normal appearance

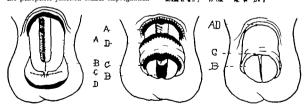

As a result of the more or less complete unnary incontinence and of the point of exit of the urne at the base of the penis the skin of the suprapuber region is constantly macerated, inflamed and at times ulcerated. The position of the penis in relation to the abdominal wall is such that the stream of urne is threeted almost vertically upward acting as a sort of sorms against the pulses.

Furthermore the direction and small size of the penus make cottus difficult or impossible, while the point of exit of the semen at the penopulus function makes impregnation

highly improbable. The restoration of the penis to as nearly normal a direction as possible is, therefore much to be desired while an improvement in the appearance of the organ does much to eliminate that sense of shame and sensitiveness which so often harasses the victim of a malformation of the emittal.

Although a simple plastic operation such as is here described, cannot be expected to a way with urlian; incontinence entirely marked improvement often takes place a feature already noted by Stettiner in an extensive survey of the literature. In babies and young children even when normal, there is little or no volition in the control of the veucal sphincter. But as the child grows older control is gradually gained and can often be developed to a remarkable degree by a system of muscle training almed directly at the sphincter. I have used this successfully for a number of years in the care of the bladder in tabetic but it must be

temembered that in epi padia one i dealing with an imperfectly developed phincter muscle

None the less uch training is to be regarded a a highly essential post-operative measure and if the patients of lenough and intelligent enough to operate there is every prospect of uccess. It is also important that the patient hould be kept under fairly regular been attended in the new tools of the patient of the vested phinter must be not ally brought to but maintained at the high tops to be post if the patient of the pat

The technique is the operation is as follows in The unchral gutter already formed is carried ut to the very end of the plands by dividing the structure longitudinally and to the jit part lepth a shown by the dotted ling Boling in the control of the properties of the modern to prevent it, edges it modern to prevent it, edges it modern to be proposed as the properties of the modern to the unit of the modern to the modern to the modern the control of the modern to the modern the mod

The prepuce alway voluminous (seen in profile in Fig. 4) it used to form a root over the urethral gutter. To the end a transverse button hole into into (C. Fig. 1) is made through it just below the fremum and extending laterally nearly to its edges. At the ame time the lower edge of the prepuce is denided by the removal of the narrow trip of kin. D. Fig. 1) and a imilar procedure is carried

D Fig. 1) and a imilar procedure is carried out on the fold of pubic. Lin which roots the urethra at the root of the peni. (1 Fig. 1)

Fig. I juspedia before speration. Peni drawn down to hoten indiport in sturethral gutter. The formatt of the puber in also hown.

The glans is then drawn through the button hole lit in the prepuce so that the denuded lower edge of the latter now comes well up on the penile shaft (D Fig.). It will also result that the glans is completely urrounded by the edges of the button hole incision (C Fig. 2). The newly formed portion of the urethra is indicated at B Fig. 2.

4 The plastic is now completed by suture of the cut edges 4 (Fig.) 1 approximated to D(Fig. 2) the inner layers (represented by a straight line) being united one to the other with No. ∞ chromic catgut the outer layer represented by serrated edges) being united in the same manner but with fine ill, or Pagen tecker linen. The unusual redundance of the prepuce allows this union to be made without ten ion. The edges of the button hole ((Fig. 2) are then sutured to one another (straight edge to serrated edge in the diagram) with ill, or Pagenstecker linen.

The completed sutures have the appear ance and position indicated in the diagram (Fig. , 4D and () while the new portion of the urethra the new meatus is een at B. The rest of the urethra is completely roofed by the plastic flap which can be readily retracted like a normal prepuce

The more or less vertical position a sumed by the penis in epi padias is to be attributed to its unusually hort suspensory ligament. While in my expensive the pla tic operation already described has been unificent to restore

Fig. 6 Roentgenogram of the symphysis showing sensuration of the public boxes.

the penis to an essentially normal position other writers (Duplay Stettiner) have spoken of the desirability of cross-cutting the suspen sory ligament and suturing it longitudinally to accomplish this purpose.

While the entire operation can be done at one sitting it has seemed desirable to do Part I as a prehminary step allowing two or three weeks to elapse before performing the more extensive plastic operation. This will allow the newly formed portion of the urethra to become thoroughly covered with mucosa Furthermore every chance should be given the wounds to heal per primam The bladder should therefore be constantly drained by an in lying catheter of the self retaining type or in the opinion of some surgeons, by a catheter brought out through a small perineal incision. The latter method how ever has the objection that in order to do this the corpora cavernosa, which in epispadias, underlie the corpus sponglosum and the urethra must be separated or mused in their permeal portion, a procedure which is not easy to accomplish and which may be accompanied by considerable bleeding

Yet in spite of every care it seems to be the general experience as it has been mine, that the plastic flaps will fall to unite at one or more points. These fistular are a source of annoyance, but can be easily closed by suture at a subsequent time

In adults the entire operation can be done with novocaine aniesthesia in infants and young children full ether aniesthesia must

be given

The following case illustrates well the
essential points of epispadias and of the
operation described.

Dg Appearance of the puns hree ears after operation. The preput be easil and ompi tell retracted and the direction of the pease is normal.

A Γ ge ; tered hospit I F bruary 4 Family hist ry no ther concental defect. Past history sumportant I esent liness Malforma tion f pens with urmary inco tin e sine The patient wet in bed Impost buth night and has lother are wet all div Sometimes be is aware that un is escaping but usually At times he goes f in hours a thout urinating D ring erects a the penns is held lose to the bd minal wall. Both testes re-n rmal alar or sistency a d sensation, nd are fully desir ded The is a typical d complit ep spadias, but th malformation cannot be fully percented the penis is dra d w by t prep The nearly vertical position assumed by the penis it small ise and it voluminous nd pro like prep ce has already been sho in Fig 4 roe tgenogram f the symphysis (Fig 6) sho very considerabl separati of th p buc bones (constant feature of all uch cases) kin is red thickened and co ered with pustules (Fig 5) The stream of urine f rms sort of speay

against the pubes but whin the pent is pulled downward the rr am can be fairly well lirected into a ba in. When the box coughts or makes any muscular effort with huses the diaphragm urine is seen to guish from the urteriar. Urine normal Training of the vest all phin ter tarted and continued daily with good response.

February 21 (an holl unne for four hours Condition of pubic skin is greatly improved since it has been kept dry. Under ether the ur thral gutter was ext nded to the end of the glans by a longitu final incision (B Figs 1 and 2) The edges of the nourd were separated by a strip of rubber Self retaining catheter to bladder was kept in place for 5 days. March 2. Training of sphincter has been continued. The patient can now hold urine in the day several hours and often passes nearly a pint at a time. He keeps lry all night by being aroused once or twice to urinate March 3 Under other a plastic was done on the prepuce (Figs 1 2 and 3) and a self-retaining cathet r inserted. There was good union of the skin edges except for a small area at junction of 4 and D through which urine leaks March 13 Durcharged but is to return for closure of the fixtula

October o oil Re-entry There is no fre quand night. The penis hangs in a nearly normal firection. The urethra now runs to the ind of the glass and the n'y formed part is lined with mucosa. The public skin is healthy. October 21—

Under ether the small fitula in plustic was closed by suture. Self retuning catheter in crted. October 10. Discharge l. To return for observation.

August 1914 seen in Out Pati in Department Ilis condition is gradly improved. The preputial hap now covers the entire urchira except at its little extremity. There are no tistulæ A tream of urin is uses from the ind of the penisochast to that the patient can stand at a urinal without wetting his clother. If says he loes not I ak lay or night and district an way for extend hours. Urin normal

can retain urine for exercil hours. Urine normal November 1914 the patient write that he has no trouble with urination

no trouble with urinatio

January 1 1016 I titent was seen at hospital His g neral condition is good Urinates 5 or 6 times a day gets up sometimes once at might There is considerable incontinence by day Jut in ver wet bed at might. He paises a good stream and tirects it well. Sex function evidently normal but has no emissions and has not attempted cottus. Plastic looks well and prepute covers nearly whologlans. Rectal examination shows prostate small but normal in contour. Vesicles not felt.

The patient has had no training in the control of the sphincter since he left the hospital. From my experience in this case and in others I do not hesitate to say that if exercises for the education of the sphincter could be undertaken with fair regularity and frequency the diurnal incontinence of which the patient now complains could be greatly improved or even entirely done away with

ECTOPIA TESTIS TRANSVERSA WITH INFANTILE UTERUS

BY ARTHUR E. HERTZLER M.D. KAMMA CITY MISSOURI

HE condition in which both testes find their way into one scrotal pouch was designated by a Lenhossak as ectopia testis transversa. But one testis of course is ectopic. The other one under goes a normal descent and is accompanied by its fellow which instead of descending into its own side crosses over to the opposite side and accompanies or follows its normal fellow.

The cause of this transposition is found in some early developmental disturbance. The nature and cause of this disturbance furnishes the most interesting problem in this lesion. Though rare some 13 cases having been described enough data is available not only to make possible some conclusions relative to

the chinical treatment of this condition but presents data of importance in the whole problem of developmental anomalies of the genito-urinary system

The specimen which I have to report made its appearance in the literature in 1907. Dr Halstead's at that time operated on the patient for herma and noted the testicular transposition. He reported it and presented some comments on the origin of this condition. His report is as follows.

D C B American single age 42 entered the Cook County Hospital in January 1904

History I atient has had a left inculnal h rails of large size since early childhood. Of lat thi hernia has increased in size until now th tumor measures eight inches from the pube pn to

Surg Gynec and Otal 907

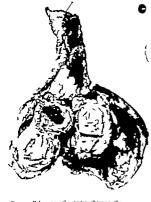

Fig. Below are the textes showing the coverings deflected to the right. Above the textes is the infantile uterus on either side of high are the epidemides.

the lower limit of the scrotum. To m the go the bernin which had previously been reducible beam treducible and painful. I add to t the hernia he has I several years been suff ring from severe hemorrhoidal disease. His object to enter ing the hospital was to secure by operative treat me triellef from both disease.

Erom alies On entrance, tuninatio housed a will developed middle grel man othing worthy of ot was found acept large left inguinal bernia distending th scrotumt the size I hald bead. Rectal exminiation disclosed the presence of large mass of lecrat og hemorrholds protrud ing from the anus.

Operation in chalc J usry 7 004, assisted by Dr. R. H. Rea house surgeon. After the usual preparation, an inclusion 35% in hea 1 mg was mad over the hearin exposing the sa. The sa was opened and the dheer t loops ? mall lutestime constitt ting the countent of the hearins are were after being freed re it was noted that the spermitte the counter of the was noted that the spermitte that it was noted that the spermitte counter the counter of the second of the seco

the tubes and ovaries attached. Upon closer inspect on it was found that the central body reoresenting the uterus, consisted of a fusion of the epididymides of the two testicies. The testicles were of closely dberent to the beads of the fused epidldymides, but wang free from the attached lower half of each with the entire mass dislocated forward into the operative wound. The fused heads of the epitidymides occupied behind and somewhat bel w the testicles. The testicles were inclosed in common tunica vaginalis. The vasa defferentia could be traced separately from the gl bus m or upward behind the fused epidsdymudes to a short distance above the globus major where they approached each other and apparently becam fused i to on cord close to the internal ring. There were two spermatic rteries and two sets of vents these were if large size and, with the large vasa defferentia and usual amount of fatty thoug greatly increased the size of the cord The test cles ere small not in size were decidedly out of proportion to the large mass representing the fused enklidymides

Exam nation sho ed the right side of the scrotum t be mpty. The right sternal ring was closed.

This patient re entered medical records by consulting Dr. A. E. Spalding of Luverne Minnesota November 1 1913. The following is abstracted from Dr. Spalding 8 report

At that tim the patient prese ted acrost in co t ining several ou res of fluid hich was removed by needle II gam prese ted himself Octobe 6 04 At this for examinati time the acrotum was as large as two fists oil was c using m ch pain. On Octobe 20, 0,4 the scrot I cont t re removed. The mass was exposed through I ng inguino-crotal incision the cord isolated and tied. This being done second cord larger that the first was sposed. This part of the cord cut lik cartilage and showed a dense-walled t be I ding t th tissu betwee that testicles. When the mass was severed coffee-colored fluid escaped

The specimen was sent to Dr L W Lating of Davenport Iowa. It was through the kindness of Dr Latting that I was enabled to study the specimen

The pedmen prese t blifd mass urrounded by thick capatle and trudates bove in a long pedunculated process. The I wer portion of the mass is mad up of two loubus which are testicular form, nilphity smaller than promit testicle and other contracts of the mass though the process of the process

is dissected off Leading from the upper poles of these are wound cords, obviously vasa defferentia These pass upward over an elongated pyriform mass. This mass is unattached to either epididymis or testic.

This body forms the most interesting feature of the specimen. It begins just above the upper poles of the testes as an elongated pyriform body 2 centimeters in its transverse diameter and 1 centimeter in its anteroposterior diameter. It gradually narrows to 6 millim ters at its termination where its tubular (Fig. 1). Its termination whow that it was severed during the operation and that the entire specimen was not obtained. When opened in a longitudinal direction it shows a trangular lumen 1 centimeter wide below gradually narrowing above. The anteropositenor diameter 10 only a millimeter or two. The cavity is lined by a smooth mucous membrane. The cut surface of the wall of this mass is a uniformly deep red in color.

The walls of this body are formed of non strated muscle fibers. The lining is a mucous membrane made up of a low columnar epithelium with simple tubular glands lined with cuboidal or low columnar cells. In short the structure is that of an elongated mignific uterus.

The testicles and appendages present an entirely normal structure

The interest in this specimen lies less in the transposition of the testis rare as this condition; than in the presence of the small uterus a condition noted in the literature in but one other instance. Case, reported be low.

Various theories of the origin of this con dition have been advanced and these are presented in conjunction with the case reports

The following brief abstracts represent all the cases that I have been able to collect from the literature. In some of the cases reported a careful dissection of the parts was not made and therefore a detailed description of the condition could not be given.

CAR 1 Reported by a Lenhossak. This specimen was removed at autopsy by the author's father in 1845. The patient was a man of 35. Both teaticles were of normal size and contour and both lay in the bottom of the scrotium on the left ade, the right however being 25 centimeters higher than the left. The vasa were differentiated a few centimeters from their origin but approached each other and became so closely bound together by connective tissue that one might have thought that they were one. Thus bound together they passed through the inguinal canal to the abdomen and at the upper and of the prostate they again became divided, the feft entering a normal seminal vesicle on the left

side the right going by a sharp angle to the right to enter a normal seminal vesicle on the right side

The author suggests that this condition was probably due to either a faulty development of the right testucle on the left side or to the action of certain forces which carried it to the opposite side. In favor of the view that the testucle developed on the wrong side are the various examples of a similar condition in the kidney. A double kidney with two ureters has been reported by Stocquart. This is an example of the transposition of an antimere

Case 2 Reported by Jordan

Patient age 8 had hypospadia in the third degree The right side of the scrotum was small being marked only by a small prominen e. The left side was about the ize of a goose egg. Upon opening the processus vaginalis at operation two testicle like bodies were noted in the scrotum from which two cor is extended to the rungs. Three months later the hernia recurred and a new hernia operation v as performed the total contents of the scrotum being removed. There was a single vas for both testicles which was large and out of proportion to the age of the patient The thi kness of its walls increased from above downward and below it ended in an ampulla which was broad, particularly in its transverse diameter. The vasa arose from the corners of this and the epidilymis was much enlarged and The right vas was normal in size and led to the bursa inguinalis to a lobule of fat vas had no epididymis, but some epididymal canals were present instead of the epididymis was present on this side

The cause of this condition is to be found in an early fusion of the wolffian ducts in that part lying nearest to the sams unogenitalis while that portion lying nearest to the testicle remained free. They dused abnormally in the same manner that the muellerian ducts normally do. The thought must be entertained, however that well-developed muellerian ducts may have played a rol. These changes certainly take place before the descensus (Examined by Klaatsch.)

CASE 3 Reported by Linser

Brn M J 90 43 2-

Patient a boy age 2 5 years. Both testicles lay in a serious cyst in a right-sided inguinal herma. The testicles lay side by side were of equal size and the epididy indicas were well formed. The wasa were separated an I found to extend to the base of the bladder but they could not be traced with certainty to the seminal versicles.

The author belt ves that there was a double an lage on the right sid and that the left had either attributed or an aplace had never formed.

atrophied or an anlage had never formed Case 4 Reported by Christopherson

Patient age 22 came to the hospital with a sweiling in the right inguinal region, extending from the external abdominal ring into the scrotum

Verthow Arch 1 path Assa., etc., Bert., Sys. harvil, #44-Deutsch med Wichoschr \$35 and, 5 5 Bestr khn. Chur 900 ands. 35

Amas Ana Jena \$56 376

Upon opening the right inguinal canal a jelly-like mass was found extending through the canal and into the scrotum. This man was about the thick ness of three fingers and mencapsulated. There were two enermatic cords coming through this same canal, one of which, traced downwards, ended in the enklidymia of the descended and very m.ch. enlarged testicle. The other cord ended in fraved out ends which were lost in the embryonic telly-like tions at the ton of the accorum. This cord lay to the inner side and behind the other cord both cords felt and looked natural and were easily accurable from each other. There was no cavity in the left side of the scrotum nor was there any sign of a descended processus vacinalis.

The anthor thinks that the fully developed and descended testicle was the left because the prostate was well developed on the left side but seemed ab-

sent on the right.

Case 5. Reported by Berg. P tient, age 13 had had a left sided rupture The right side of the scrotum was poorly developed and there was a large scrotal hernia on the left side. At the bottom of the left half of the scrotum was a fair-sized testicle, its free concave border pointing downward. From its right pole a normal-sized cord passed upward to near the root of the penis, then curved sharply to the left and was lost near the opening of the hernial ring. When the patient coughed slightly a smaller testlicle could be felt at the left external ring which could be pulled down into the scrotum. A cord named from it into the hernial ring. The right external ring was very small and no cord could be felt to enter it. At operation both testicles and cords were found to be intimately connected with the hernial sac on the left side. Both cords passed through the left inguinal canal. The upper testicle was the smaller and its cord had a distinct mesentery This cord passed up into the left inguinal canal through the internal ring, across the space of Retzius t the right inguinal region where it de scended to the pelvis. The larger testicle lay in the bottom of the sac its cord passed up into the left inguinal canal and descended on the left side of the bladder to the pelvis. The right internal ring was exposed and found to be closed. The scrotum showed no evidence of division into two compart ments. Both cords and testicles were treated as one and the radical hernia operation completed in

the usual manner CARE 6 Reported by Romanowski and Wini-

warter

Patient, re 61 died of pneumonia. On section there was noted a fold which extended from the fovea inguinalis lateralis across the anterior wall of the pelvus, behind the upper surface of the blad der, to the left of the foves inguinalis lateralis where it disappeared. The plica differentialis was absent on the right side but was well developed on the left.

The right side of the acrotum was empty The external ring on this side was very small and out of it came a small connective ties e band which ended like a ligamentum teres. On the left skie the external ring was m ch enlarged and the cord thicken ed. Upon opening the sac two testicles were noted the right situated slightly above the left which was small and deformed. The right was larger and less deformed but had the coldidymis on its summit, from the center of which the was arose. The processus vasinalis was open to near the external ring but from this point on it was completely obliterated. The left was run its normal course to the base of the bladder and into the seminal vesicle. The right vas however tra eraed the bladder obliquely over t the right skie its course corresponding to the place differentialis already noted. The right spermatic vessels arose at the normal place and denormal course to the linea terminalis. from which point they followed the previously described pentoneal fold from right to left to the left ring A subernaculum Hunteri could be traced from the external ring through the canal and across the summit of the bladder in company with the westels.

The uthor thinks that there must have been some bnormal connection between the two testicles which made it possible for the left to take the right

with it in its descent

Cas 7 Reported by Cornil and Browned

Patient age o, had a uterus in the tunica vaginalls which was united with two testicles. This uterus mensured o. v centimeters in length the body being larger than the cervix and the walls somewhat thickened. On one sid the tube emerged normally but became dherent t its extremity to the textele On the other side the corn of the uterus was united to the testicle by a fibrous mass. On section the uterus the walls were found t be thick, the mucosa congested and presented transverse plica tions separated by ridges millimeters in diameter

Histological esamination. () Uterus. On sec tion it was found that the transverse plications represented numerous glands and tubes lined by a tall epithelium. Between the depressions the moosa was thicker rich in small cells and contained fewer glands. T ward the body cavity the mu cosa was more papillary. These papules were formed by inflammatory tissue with hypertrophied giands lined with tall epithelium. () Testicles. Sections made at the point where the tube attached showed a normal tube and epididymia united by connective tissue. The testicies were normal and spermatogenesis very active. The fibrous band going out from the opposite comu showed his wise

tube and epididymis united by fibrous tissue There was not the vestige of an overy Section of a cornu showed a tube in its interstitial these.

This condition was due to a diversion in development consisting of an increased development of the uterus due t the fusion of the muellerian ducta.

Bell Acres de mart Par spery and hope, at

And Berr Phile 1904. El. 13-

Armit Ann June, 1905 2271, 6

The wolffian and muellerian ducts must have developed side by side because they were united by a common connective-tissue envelope

Case 8 Reported by de Castelli

Patient age 23 came into the hospital to be operated on for a right sided herma. The herma was congenital and had gradually increased in size and become very painful. The left side of the scrotium was found to be empty. The right side contained two testicle like bodies which were painful on pressure. From these came two cords which disappeared into the inguinal ring. At operation the cord was exposed accompanied by the artery and veins. Within the canal was a testule and from this ran a fibromuscular cord connecting it with a second testucie in the scrotium.

CASE o Reported by Bottaro?

Patient age 13 had no history in his family of herms or testicular anomalies. An oblong body about the size of a walnut was noted in the right inguinal region. This was somewhat sensitive and was reducible but a part of the mass remained in the inguinal canal. The left inguinal canal was found to be free and a disgnosis of abdominal retention of the left testicle was made. At operation two cords and two vigunal processes were noted extending down the inguinal canal one going to a testicle in the scrotium the other to one in the inguinal canal.

CASE to Reported by Lowe

Patient age 3 was brought to the hospital to be operated on for a left ingulnoscrotal hernia. The hernia appeared to be congenital but no reliable history was obtainable. When the structures in the canal were being isolated from the sac two cords were discovered and these were traced to two testicles lying in the acrotum. They were each the size of a normal single testicle. After the sac was ligatured the testicles were returned to the scrotum. After this reduction the scrotum appeared highly

Raforma med 000, xxv y y raf Jahraab d. Fortachr d
Out 000 00

Brit M J 0 515.

unsymmetrical the left side being very full and the right quite empty

Case 11 Reported by Marsh 4

Patient age 3 was operated on for a large con genital herois of the left side. Upon exposure of the ring two cords were found passing down to two testicles which were inclused in one tuni a varinglis. The child died of ho & some 36 hours lat r and at autopsy a careful dissection of the part, was made There was only one year pla seminalis, situated on the left side and it was considerably larger than normal. In connection with it was a very large vas as thick as an ordinary drawing pencil which took the normal course as far as half an inch from the internal ring, where it divided into two of equal size which passed down the inguinal canal into the scrotum to the two testes. The right spermatic arters crossed over the middle line about three inches below the umbilious and meeting its follow of the opposite just inside the int rnal ring found with it to form a single trunk. This trunk divided again before reaching the external ring the two vessels being distributed to the testes in the ordipary manner

CABL 12 Van der Horn van den Bos presented a case in which incidentally in the course of a herma operation he found that both testicles had passed through the right inguinal canal into the right side of the scrotum

CASE IX Reported by Widhalm 4

Patient age 4 was married and had three children. The right testicle was somewhat atrophic He had had a hernia on the left side since childhood. The sac was filled with omentum and there was marked cyst formation. There was a hydrocele about the size of a fist on the cord and lower down a smaller cyst which contained two testicles of equal size. Behind they were united by a band form epididymis and off from this came two independent vasa.

PRIMARY CHORIO-EPITHELIOMA OF FALLOPIAN TUBE FOLLOWING RUPTURED ECTOPIC GESTATION

BY HARRY J HARTZ, M.D. PRILADELPHIA mirrator of Gynacological Pathology Jefferson Medical College

RIMARY chorio-epithelioma of the frequent occurrence when we take into consideration that tubal gestation forms but a small proportion of all uterine preg nancies. Of approximately 300 cases of chonoepithelioma that occurred up to 1005 the primary tubal variety comprised about 3.5 per cent of the total number

In 1005 Risel (1) made an exhaustive study of primary chorlo-epithelioms of the tube and collected II cases in the literature which he reviewed in great detail. He reports an interesting case of a woman 35 years of age in whom apparently a chorlo-epithelioma followed a tubal abortion.

The woman had had three rmal labors, the youngest child was five years of age For bout four months after the onset of vaginal bleeding a bloody tumor measuring axaxx centimeters, of left t bo-ovarian regi n was emoved. Six weeks after operation symptoms of intestinal obstruction developed and one month following the onset of symptoms, operatio disclosed an inoperable bloody tumor in the pelvis between the uterus and rectum. Shortly after operation, the woman died, seven months elepsing between the advent of symptoms and fatal termination. Post-mortem examination showed the genitalia and uterus free from the growth but numerous metastases were found in the liver and both lungs.

In addition to the above 11 cases recorded by Risel, Leipmann (2) adds 7 more making a total of 18 cases of primary chorio-epitheli oms of the tube up to the year 1914. In Rosaier's (1) case reported in 1912, the tumor attained the size of a man s head. In one of the two cases reported by Davidsohn the tumor developed in the stump of the tube which had been removed for a ruptured ectopic gestation. Lefquist's case is also auite interesting

In 1006 the patient was operated upon for tubal pregnancy The tube was cleared of all gestation products but was not excised. Two years later a pregnancy in the same tube recurred, and at opera

tion the tube was removed. P thological examina tion revealed an early development of a primary chorle-epithelioms of the tube.

In the majority of the cases reported recurrence was the rule the patient succumbing to the disease but in a comparatively short time after onset of symptoms.

The case that I am reporting was operated upon in St Joseph's Hospital by Dr P B Bland and was referred to him by Dr Koplin of Trenton New Jersey The following history was obtained.

A S 34 years fage, white, married She becan to menstrust at 3 years, was regular and ormal The patient was married for twenty years had six normal pregnancies and four abortl as. The last pregnancy terminated abortion four months prior t th onset of ymptoms. F two weeks the patient complained of vaginal bleeding accompanied by severe cramp-lik pains in the lower abdomen. A diagnous of ectopic gestation was made and operation dvised. The operation was performed in December 0 3 The abdomen was opened. The right t be showed pregnancy with rupture. The terus was enlarged and soft and was the size of pregnancy of about six weeks. The tube and ovary wer removed and the abd men was closed. The pathological report f the speci-

men is as follow The mass consists of t be and ovary and gestation sac i collapsed condition. The t be measures 5 centimeters in length and 4 centimeters in diameter at its widest portion which is situated near the ambelated end. The lumen is filled with clotted blood and the walls of the tube are considerably thickened. Between the lo er border of the tube and overy there is an irregularly haped as in col lapsed condition measuring 5 centimeters i diameter and lined by a shaggy dark red, membrane. Ad herent to these haggy villous-like projections are masses of clotted blood. Under the microscope sections f the tubal wall show an trached placents. At points the chononic epithelium extends into the thin wall of the tube for som distance and there are masses of these cells in the lumins of some of the veins. This involvement of the wall of the tube is m re extensive than usual and justifies the term chorio-enithelioma.

Diagnesis Primary chorio-epithelioma of tube following ruptured tubal gestation.

Two years after operation the patient is in the

as health. Her menses are normal, lasting three four days. Her work is ardious assisting her laband in a grocery store from early morning titl late at night besides which she attends to her gular household duties and takes care of her hildren and with all this hard work she says she as never felt better in her life.

Leipmann strongly emphasizes the fact nat sharp differentiation should be made etween primary chorio-epithelioma of the abe and the so-called ectopic chorio-epi elioma The term ectopic chorio-epi nelioma should be reserved for only those ases that designate the location of the nmary growth in other structures and away com the ovumnidus or placental site and enterates that it is incorrect to apply the erm to primary tubal tumors that originate t the placental site. Metastatic or secondary rowths occur from the tubal growth just as eadily as they do in uterine variety Iso after a tubal pregnancy an ectopic horro-epithelioma of primary growth remote rom the tubal placental site has been de cribed

Primary chono-epitheliomatous tumors emote from the placental ate of the uterus and fallopian tubes have been observed in I cases by Findley In no instance was it possible to trace a direct anatomical connection between the placental site and the primary tumor. The tumors arose during the course of pregnancy at varying periods after the completion of normal pregnancy and following complete and incomplete abortions In nearly all cases it has been possible to trace a direct clinical relation between the pregnancy and the tumor formation vagina is most often the seat of secondary invasion of metastases in cases of piimary chorto-epithelioma of the placental site but it is also true that it is the most frequent site of a primary growth. Findley reported 14 such instances in the 21 cases collected by him The interval between the last known pregnancy and the development of a choroepithelioma varies considerably. It usually

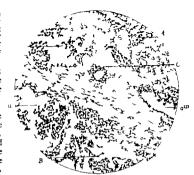

Fig. t. Primary, h. rs. epithelioma, i. tallopian tube followin, rupt, ed. t. bal gest tion, i. u. o¹² neoplastic cells in lumen of blood. e>el. B. tubal lumen C. pen ascular small round, ell inhitratio

occurs shortly after the termination of the pregnancy or may be delayed several years after the last labor or abortion. Recently Outerbridge (6) reported a case of a primary chorio-epithelioma of the vagina that devel oped eight years after the last known pregnancy. In one of the three cases of chorio-epithelioma of the uterus that I exhibited before the Pathological Society of Philadel phia last year the tumor developed at the placential site in the uterus six years after the last known p egnancy. The onset of symptoms in the patient developed three years after the menopaus had occurred.

CHONDROMA OF THE PELVIS¹

BY J HUBER WAGNER, M.D. PETTERUROR

ten upon true chondroma and other forms of cartileginous tumors arising from various parts of the body These tumors whether enchondroms, ecchon droma, osteochondroma, chondrosarcoma, or esteochondrosarcoma were, by most auth ors and especially those of the earlier times. classified as enchondroma. Since 1816 when Ican Muller gave the first complete description of enchondroma, until the present day a hundred or more articles upon the subject are readily found in the literature. Most of these articles appeared in the French and German literature before 1800 Since then relatively few reports have appeared and only a few of them, dealing mostly with the report of cases, in the English. In this paper I have attempted to summarise the work of others as well as give a description of three cases of enchondroms of the pelvis coming under our observation.

TUMEROUS articles have been writ

Chondromata are tumors composed of cartilage-cells with a varying amount of matrix and connective tissue stroma. These tumors may be composed of any of the three types of cartilage, hyaline, elastic, or retucular or may be composed of any two or all three types with variable proportions of each. However the tumor most frequently met with is that of the hyaline variety. In the latter there is an attempt to reproduce the true hyaline cartilage, with relatively few cells scattered sparsely throughout a homogeneous matrix.

Classifying chondromata according to their manner of origin they are spoken of as ecchondromata or enchondromata. Ecchondromata are outgrowths of cartilage occurring in regions where cartilage is normally present, as in the region of a joint, the larynx or trachea. Such a tumor results through a process of hyperplacks or overgrowth of cartilage. Ecchondromata are homoplastic. The enchondromata on the other hand are masses of cartilage or cartilaginous tumors having no

connection with areas of normal cartilage formation These are considered under the heteroplastic group and develop where cartilage is not normally found.

In the gross these tumors vary considerably in shape and size. They are as a rule, irregularly globular and range from the size of a hazelnut to a mass 100 centimeters in circumference They may be single or mul tiple. As a rule and especially those which attain a large size present a lobulated surface and are attached to the parent tissue in a They are surrounded by a sessile manner capsule of fibrous connective tissue which sends trabeculæ into the tumor dividing it into many lobules of variable size trabeculæ carry nutrient blood and lymph vessels. In color these tumors vary from white to bluish gray

On section, the cut surface presents a blutch ground glass appearance in which white bands of connective tissue divide the tumor into various sized lobes. In consistence the enchondroma is elastic, but this may vary from a soft and gummy character to bony hardness.

Degeneration of these tumors due to the limited supply of nourishment of those por tions of the lobules most removed from the trabeculæ which carry the blood and lym phatic supply is quite frequent. The de generation may be myxomatous calcareous or fatty and in frequency occurs in the order named Occasionally a well-defined mass may undergo myxomatous degeneration leading to the development of a true cyst, or the whole tumor may be composed of a myxomatous matrix in which very few cartilage-cells are seen, a myxochondroma. Some specimens show the deposition of calcium salts in the matrix with a shrinking of the cartilage-cells giving rise to a type of calcareous degeneration but without bone formation. degeneration is described by some authors as an overabundance of fat droplets in the cel lular cytoplasm, where it is normally present.

Degeneration is more likely to occur in those tumors of the homoplastic group or ecchon dromata where the trabeculæ are not so abundant and where there is less tendency to form lobules

The pelvis in view of its embryological development and numerous centers of ossin cation, its articulation and relation to other parts is a not uncommon site of chondromata and has many locations from which they may arise. These are (1) from cartilage of the ischiosacral synchondrosis (3) from the cartilaginous disc at the sacrovertebral ar ticulation and (4) from the cartilage of the acetabulum. The tumors arising from the above named places are of the exchondromagroup.

cell rests which may be located at (1) the junction of the ascending ramus of the ischium and the descending ramus of the pulsis (2) the junction of the acetabulum and the ilium ischium or os pubis (3) any portion of the pelvic bones where connective tissue exists or (4) the tumor may arise by extension of growth from the surrounding parts. These arc of the nature of enchondromata

Clark reported one case of chondroma of the pelvis occurring in a middle aged woman This was fir t observed as a tumor above the hip and in the presence of other signs a diag nosis of medullary cancer of bone was made. The patient became rapidly emacaited anar mix and died. At autopsy all of the os in nominatum was involved in a tumor mass. The tumor measured 8½ x 9 inches filling the pelvis and displacing the rectum, vagina and bladder. Microscopic examination showed the tumor to be entirely composed of cartilage and its malignancy was due to its position.

An enchondroma of the pulvis developing at the site of injury was described by Potter The patient was a female 37 years old who gave a history of a fall ten months previously and two day before continement. In falling site struck her buttocks on a stone floor The injured area was quite painful and tender for a few months. Five months after the injury she noticed a small hard swelling on

the right buttock. The mass enlarged and grew along the ascending ramus of the ischium and descending ramus of the pubis reaching the size of a six months feetal head. It filled the pelvic outlet causing difficult urination and defectation and preventing intercourse. At operation the tumor had an irrigular surface and was covered by a fibrous capsule. Microscopic examination showed it to be composed of a fibrillated cartilage frequently showing several cartilage cells in single lacuna. Many areas of calcareous degeneration were present in the tumor.

Several other similar cases with a history of trauma at the site of tumor formation have been described by Halthouse and others In his researches Wartmann described eight enchondromata two from the pelvis four from the hand one from the lung and one from the parotid gland He has studied some five thousand sections of these tumors with the following conclusions He confirms the opinion of Virchow who indicated that enchondromata arise from connective tissue He also claims that by a process of metaplasia the endothelium of lymph, and blood vessels may give rise to enchondromata and further that many chondromata arise from cartilage nous emboli within the blood vessels

The following are three cases of enchondromata of the pelvis which have come under our observation. The first two originated in the pelvic bones while the last had its origin in the femur and by metastasis extended to the pelvis.

CASE I Mr E. H K ago 38 years Occupation, farmer (white) He has always had good health. Two years previously the patient received a sharp injury by being thrown on an iron rod. It did not trouble him much at the time, but later he noticed a small growth at site of injury.

On examination there was found on the inside of the left thigh and below the perinceum a hard im movable growth about the size of a mans ist ad herent to bone. The soft issues over it were not involved. The glands were not enlarged. He was not inconvenen-ed in walking. There was slight pain which radiated toward the knee. There was no ca bean nor loss of weight. His general condition was good.

An operation was undertaken under general anes

thesia. In incision was made along the inner side of the thigh trans erse to the tumor. The tumor which was adherent to the ischium and arose from the ascending ramus was chiscled away from the bone and some of the tissue in the neighborhood was removed. Recovery was good. The patient left the hospital 4 days after entrance and thirty

nine days after the operation.

Pathological examination. This tumor was a large mass about the size and shape of a man a feet. It measured ox 75 x 6.5 centimeters. The sur face was very irregular and nodular. It was composed of nodules varying in size from pin head to a marble. The tumor was covered by a carryle of dense connective tissue of a glistening character Scattered diffusely over the tumor mass were mail lobules of vellow fat. These were bound to the fibrous tissue capsule. Over about one fourth of the surface the careule was missing. Here the tumor had been separated from its attachment. This part was very rough and had many fibrous tags hanging to the surface. I many places it had the appearance of the pulp of an apple and was finely granular This cut portio was studded with fine chalk lik areas varying in size from pin head to a large nea or bean. These areas were very in regular in outline and of a calcareous nature

On cutting through the tumor it was found to be composed of ma y distinct nodular masses of car tllage. Each mass was definitely outlined but was united to the neighboring lobules by dense fibrous tissue. The cut surface was of bluish gray olor and had a finely granular or frosted ppearance. In the center of several of these there were irregular chalky mames of calcificatio Throughout the tumor there were thick strands f d se whit

fibrous tissue

Microscopic sections of the temor howed to be mainly composed of cartilag and fibrous times The latter save for the main trabecular as small in amount and passed through the mass : all directions, dividing it into small I bules. This con nective-tianu stroma was loosely arranged and co

tained relatively small number of nucles. In some parts of the sections the lobules of cartilage were mainly composed of a clear hyahne matrix in which the cells were sparse. The cytoplasm of the cells was contracted leaving almost vacant lacung save for the centrally placed nucleus Again in other places the cells were more bundant and the matrix less in amount. This did not have the appearance of mature hyaline cartilage but had a strenked appearance due t prominent fibers in th matrix. Here the cartilage was not arranged in the well-defined lobules, but had an irregular architecture with ill-defined borders. At times it was difficult t differentiate true cartilage-cells from the fibrous connective-tissue cells of the trabecular.

At the border of the sections and adjoining the fibrous stroma, the cartilage-cells were lying in meshes of collagen fibers of the connective tissue but as one advanced from the fibrous trabecule the cartilage-cells took on a more mature appearance and the collagen fibers became fewer in number gradually disappearing from the hyaline matrix. The cell walls were very industinct and could not alw vs be made out. This was particular ly true where the cartilage was more mature. In other parts of the specimen, as many as ten cartilagecells were urrounded by a single indented capsule. Diagnosis Chondroma of the ischi m.

Mr Jos. B age 5 years. Occupa CASE tion, carpenter (negro) Patient had been in rood health until 8 years ago (34 years) when he had typhold fever He made a good recovery and was perfectly well til five years ago (47 years) when he had trouble with his bowels and was compelled t use nurreatives. Gradually but slowly constina tion became more marked. Two years are he had frequency of mict rition, associated with some pel vic nain. Gradually but slowly his condition became worse. Si months ago he noticed a hard firm enlargement have snine of the left public bone. Being a curpenter be timbuted the development of the mass to injury occasioned by the use of n auger This tumor gradually became larger One month ago he noticed a similar mass t the right of the publs. progressively becam more constituted and

nnation was more free ent. He has not lost me ch (if any) n weight

On examination h preared t be fairly wellnourished man. A firm tumor was found project ing above the pubis on either side and filling up the anterior portion of the pelvic cavity The finest could be inserted into the rect m fo dist no of bout one inch. There appeared the but a small space posteriorly to the bowel Examilation eligited no tend mess.

A large odula mass composed f I bules of bluish what color was removed from th posteri surfa e f the horisontal rami f the public bones. The t mor extended laterally on both sides of the ymphysia. The nationt made an uneventful

COVERY

Pathological ex m nati m The tum r mass was ery rregular and nodular and composed of various kinds of tissues. It had the shape of a large potato and measured 3 x 7 5.5 centimeters. The tumor was covered i an irregular manner by a fibrous capsule t which many fibrous tags were attached. There were may thick fibrous bands running over it in various directions. I places the tumor was of firm bony consistency in others it was m re elastic and at times it even appeared cystic. There were about thirty smaller pieces of tumor which during removal had been separated from the main mass. They varied in size from a walnut to one-third the large tumor and were similar to it in structure

For the most part the tumor was occupied by lobular masses of cartilage which had a dense bit ish white, glistening appearance, and surrounded by a definite fibrous capsule. On section, some of these masses of cartilage seemed to coalesce with the neighboring masses. In other parts, they existed as separat lobules and were attached only through intervening thick bands of fibrous connective tissue. These bands traversed the tumor in all directions nd appeared to an e from the surrounding throus apsule. On closer inspection this arrilage was a fullsift-gray color it was mooth and had the apearance of frosted gla. The arrilage was a quite dissit. In another portion of the tumor, there was ome firm white calcined its ue which was irregular ind nodular representing or suggesting cal in atton of definite arrilaginous notifies. These alcined treas could easily be broken into mall nodular masses each of which was separated from the next nodule by a cap ule.

Attached to and embedded in the dense abrous agould was a mass of fat which was or a dull vellow solor. On section through the evan portion of the sumor the interior was found avitated in a very irregular manner. These cavities extended through the tumor mass in many directions. The artilage nous sub-tance in this region and urrounding the cavit was very soft and easily broken. In the thirk bands of connective tissue were many connected blood vise els. The tumor had in place a dested blood vise els. The tumor had in place as

oink hue

Mi roscopic sections of the tumor showed it to be omposed of a h aline cartilage. The cells were of van us izes and shape and lav in laturar sur rounded by a matrix of varying consistency. Groups of cells losely or loosely arranged were found The cells were mostly oval but a gradual transition from stellate to o al forms were also frequently seen Some of the cells were surrounded by a capsule or the kened portion of the matrix. Others showed no capsule hatever and still others showed a single capsule surr unling from three to twelve ells. In some of the cells a time network was seen extending from the contra ted entral mass to the cell wall Running through the tumor were strands of abrous connective to ue which contained blood essels Several of these were seen to change by gradual transition into artilage ells of the hvaline variety The artilage gradually assumed a more adult type as one all an ed from these fibrous trabeculæ in ward. The matrix of the cartilage had a homogeneous pink hyaline appearance. In some places howe er minute abers could be distinguished in this substance.

Case 3 Mr S age 18 years O upation, student (white) For the clinical report I am in debted to Dr B Z Cashman of the St Francis Government of the St Francis goveth was noted on the external surface of the night femur. Two months later this had extended to the inner side of the shaft. The patient lost nive pounds in weight during the last few months. There had been some pain in the femur for the last month and some disconfiort on the side of the right hip.

A tim mass was found over the inner part of the right thigh from trochanter to middle third. There was no pain on pressure. No change was to be observed in the overlying skin or vens. No other mass was present in the pelvis. The \text{\chi} ray showed an egg-shaped softening below the greater trochanter. On January 21 1913 & small piece was exceed.

for examination and a diagnosis of chondromyxoma wa made. I no anda wa added suggesting hability to recurrence

An operation was undertaken for the removal of the growth. The mas was easily tripped from the femur and pelve by the hand. While removing the tumor a sensation like running the hand through a bol lot it ked it was obtained. The operation was followed by treatment with the a tual cautery latin its harged fet runn 5.

March t 131, One and one halt months later a mass the 12 of the original was found beneath elut us maximus and atta hed to the femur and as also removed and auter i hum This mas uzed April 3 1015 No eviden e of recurren e April 1 131 A mass v.a. noti ed below the de seen ling ramus of pubicand attached to the temur Patient was referred to an \ ray expert who treated the ase for four weeks with \ rays The mass became softer but larger. The patient then sustained a pathological fracture of the femur. A sinus developed and blood drained from the area of injury The patient was treated at Baltimore for 43 hour continuous radium. The mas con tinued to grow October to 101, Patient home Marked cedema and redness over the mass which appear smaller General health somewhat im prov d. February 1016 Patient autopsy

Patkel 1 al r port (Tanuary 101 were received numerous small irregular pieces of soft cartilaginous tissue representing a tumor about the head of the femur. The largest of these masses was 4 x 3 x 5 entimeters. These pieces of tis ue were of a pale translu ent appearance. The tissue was of the peculiar consistence of young carrilage and was quite friable. Running through it were strands of abrous tissue forming trabeculæ and carrying small blood vessels. The tissue was or a uniform structure and appearance. The cut sur face was smooth glassy and hrm to areas of necrosis were observed. The tissue was distinctly translucent and in the smaller pieces which were very numerous and sometimes blood stained, the abrous trabeculæ stood out quite prominently as opaque, white strands A nrm stroma was seen to penetrate the solid gelatinous substance from these trabeculæ In many of the smaller piece the surface was gritty owing to the presence of small particles of calcium salts. One small piece not over 1 entimeter in diameter consisted chiefly of omnact can cellous bone. This was covered on one surfa e by the cartilaginous tissue

Mi or opic Sections of the tumor mass showed it to be composed of a matrix of a by aline hara-ter in whi h man cartilages-ells were found. These ells were of irregular size and ship per some being out large and multinucleated. Man were spher is all having a wide protoplasmic rine and contracted laruna. Others were rather spandle shaped or stellate. No mitot'c figures wer observed. The cells were trather loosely distributed and nowhere

tion and growth of bony and cartilagmous parts are much retarded.

Enchondromata may also result from an

Enchondromata may also result from an inclusion of cartilage-cells (anlage) during the development of certain organs. Those likely to occur in the pelvis are enchondroma to of an undescended testicle or an ovary. These organs are developed in close apposition to the vertebral column and may include an anlage of cartilage from the intervertebral discs, which later may take on the power of growth and give rise to a tumor. This was shown by Virchow to be the probable source of enchondromats of the parotted gland in which an anlage or inclusion was obtained from the learnchild arrhes.

Francois reported a case of enchondroma of the ovaries occurring in a patient 74 years of age, but does not give any view as to their mode of origin. On the other hand Wart mann in his classical researches upon enchon dromata has observed and described the endothelium of the blood and lymph-vessels retroverting to a type of embryonic mesodermal tissue from which it then developed into carrillage-cells and formed tumors.

Enchondromata of the pelvis usually de velop during the third and fourth decade Of the 60 cases reported in which attention was called to the age of the patient, 46 have occurred between the age of 20 and 40 years, and 20 of these between 30 and 40 years. Considering these tumors in the order of their frequency in particular locations those arising in the pelvis stand fourth the bones of the hand femur and tibia respectively being more frequently involved in the order named In these latter locations, they very often are the late outcome of arthritis and particular ly of arthritis deformans. Heredity seems to play little or no part whatever in the development of chondromata, although those occurring on long bones have been found in three successive generations. These tumors occur about equally in both sexes. Of 105 cases reported, 50 occurred in females.

Considering these tumors in regard to their rate of growth and duration one can say very little, as they are usually removed surgically at an early period. However one can say that they are, as a rule, of slow growth, but

may suddenly take on the qualities of rapid growth and cause the death of the patient. Livert in his statistics on enchondromata in general taken before the days of modern surgery reports 12 cases issting from one month to two years before death 11 cases from two ten years 12 cases of ten to twenty years duration and 3 cases more than forth years duration

forty years duration Many enchondromata of the pelvis are clinically malignant mainly because of their position in relation to the various pelvic organs. This was the more true before the days of antiseptic and aseptic surgery when the tumors were allowed to develop to an enormous size Some of these tumors possess characters of true malignancy as is shown in one of our tumors having metastases. This process it is pointed out by Wartmann. takes place by the development of buds which grow into the lumina of vessels are broken off and carried to distant parts organ most frequently involved is the lung Some of the tumors spread to distant parts by continuity and in this way show their malignancy. This is more ant to occur in tumors of a soft character whose cells are irregular in size and shape and simulate in appearance embryonic cartilage-cells. The matrix of these tumors is soft and of a gela. tinous nature often myxomatous. This is well shown in our Case a with metastases involving the pelvis. Francois cites a case reported by M Dolbeau showing a metasta sis of enchondroma of the tibia to the pelvis. The more cellular these tumors are the more prone they are to develop typical sarcomatous masses of fibrous type.

Gibbs reported a case of enchondroma in the breast of a bitch growing side by side with a surcoma, but having no connection with it. In some instances it was impossible to differentiate the two types of cells save by special staining methods. It is possible that many cases of this kind with metastases and other signs of malignancy have occurred in the human, and hence reported as malignant enchondromata.

Enchondromata may be differentiated in the gross from similar growths by observance of the following These tumors are definitely

MALINIER

outlined and globular in shape while malig nant tumors are irregular in shape and out line Pain is not so marked if present at all and not of the lancinating type as some times found in malignancy I aim in exostoses is present from the beginning while in en chondromata it is absent until the growth is quite large. There is no involvement of lymphatics and only in rare cases are the blood vessels engaged. Keen is of the opin ion that enchondromata arising in children are usually benign while those arising in later years are more hable to become malig nant.

From our experience and study as well as that of others it is evident that enchondroma. ta of the pelvis most frequently arise in fibrous connective tissue and develop through a process of metaplasia following a stimulus usually a definite injury Furthermore their clinical malignancy is mainly dependent upon their position and only rarely do they adopt a sarcomatous character and show true tissue malignancy I wish to acknowledge the valuable assist.

DEPARTMENT OF TECHNIQUE

THE APPLICATION OF ANOCI-ASSOCIATION TO OBSTETRICS

THE COMMINED USE OF SCOPOLAMINE NITROUS-ONIGH AND LOCAL INSILTRATION

B CARL L. HOAG M.D. SAN FRANCISCO Arbitrary Investity of California Michael Related

IN a paper read before the Pan American Medical Congress last June (r) I pointed out the way in while the principles of anocassociation could be applied to obstetrics. I wish briefly to review these points before reporting the results of my work since that time.

The principles of anoci-asociation are too will known to need description here. The ac ceptance or rejection of this system constitutes one of the most warmly debated subjects of present day surgery. There are those who are firmly convinced of its mentis and others equally sure that it is only a fad, soon to follow the numberiess panaecas once halled with enthusiasm but now forgotten. Whatever may be its future as a system it has already left its mark upon the technique of every clinic in promoting the more carrful handling of tissues, sharper dissection and

reduction of trauma.

The principal objections seem to be that there is a lack of muscular relaxation under nitrous-oxide-oxygen, and that there is difficulty in securing it by local nerve-blocking.

During the part three years it has been my good fortune to study a large number of cases operated under nitrous-oxide-oxygen and anod association. This experience has convinced me that success depends almost entirely on the care and thoroughness with which the local infiltration is done and those who have succeedabave done so by making the nerve-blocking as complete as that necessary for operation under local anesthesis alone.

Since the appearance of the articles by Webster (a) and Lynch (b) in March, 1915, the use of intross ordice in obstetrics has rapidly increased. When we remember how many surgeons have discarded it on account of the lack of relaxation in the abdominal wall we cannot help feeling that the percentage of severe perined team must rise, unless the pelvic muscles should happen to be very different in their reactions under the gas. Since there are no reasons for expecting such a

difference, I bele e we should be prepared to meet the difficulty. One way would be to change to one of the more relaxing anesthetics such as ether or chloroform at the time of delivery another would be to use nerve blocking locally If relaxation can be secured in the abdominal wall by the use of novocanne and quinn ures, it seems likely that the same results could be obtained in the perineum.

Of the 30 cases receiving perineal injections, so were given nitrous-oxide only Group I four were given nitrous oxide-ovygen until the time of actual delivery when chloroform or ether was substituted. Group II and six received chloroform in the usual way Group III. The perineum in all cases was injected with o 25 per cent novocame varying in amounts from to to 150 cubic centimeters Eleven recei ed in addition from to to 40 cubic centimeters of per cent quinin urea solution each. The maximum amount of the two solutions injected in any one case was 175 cubic centimeters. The injection was made as the head appeared in sight. The vulval edges were turned back and a long needle was inserted at the mucocutaneous border the fingers of one hand being in the vagina to note its position. At this period the perineal floor is flattened out by the oncoming head, but not stretched to any degree. Even though the field is large both the levator ani muscles and the perineal body can be readily infiltrated. Novocaine was injected first and the quinin-urea immediately afterward.

For the purposes of this paper we are concerned chiefly with the so cases in Group i that received nitrous-oxide-oxygen only. Seventeen of these received from one to five doses of exopolamine during the first stage before nitrousoxide-oxygen was begun. The initial dose of exopolamine was 1/200 grain or narcophili ½ grain. This was followed usually at irregular intervals by the same dose of scopolamine without the

morphine or narcophin. In four of the prolonged labors a second smaller dose of either the morphine or narcophin was given. These drugs were given inst to reduce the amount of gas used and secondly because many of the nervous pattents became more quiet and took the an asthetic better.

It should be emphasized that an excessive amount of scopolamine often proves worse than none because the patient must be mentally clear to give the proper co-operation with gas analgesia. In none of these cases was the amount sufficient to produce anywhere near the mental condition observed in so-called tv1 light sleep. I believe its use in these amounts is just as advisable in obstetrics as in general surgery and for the same reasons.

Nitrous-oxide-oxygen analgesia was begun before the end of the first stage or at the begunning of the second according to the distress of the patient and to her ability to pay for the gas

Fair There was a marked difference between the private and the clinic patients in regard to the success of the procedure as far as pain is concerned. The private cases all intelligent women schooled in the part they were to play and at tended by professional anæsthetists suffered very little. Some of them had absolutely no pain others asked for more anasthetic and complained of distress but after it was all over could not remember having had much pain. In the other group of clinic cases conditions were less favorable. The women were less intelligent some could not even speak English. With the first few cases the anæsthetic was given with a new type of machine by men unskilled in the use of gas. Under these circumstances in some cases the gas did not give enough relief so that choloroform or ether had to be substituted These are the cases that make up Group II Later better results were obtained as regards analgesia but still not as good as in private cases

During the delivery of the head analgesia was succeeded by complete anæsthesia in all cases. I believe this is an important point it greatly lowers the danger from those sudden expullive contractions which so often produce tears. It has been found advisable after years of experience with chloroform and I do not see why it should not be used with nitrous-oxide-oxygen. In fact, the indications for complete anæsthesia are greater with such a light anæstheti.

In the first so cases, delivered under nitrouscoxide-oxygen and anot slone infection were primipara and the other a II-pera. The agrevaried from eighteen to thirty-one, the average was twenty three years. In all but one, the position was left corpito-emetior oright cochpitoanterior. One was a right occipito-posterior which pensisted and was delivered as a brow with low forceps. In spite of this complication, the nitrous-onde-oxygen worked actastically.

Length of labor As far as they go the former in the nitrous-oxide-oxygen cases indicated shorten ing of the second stage. The time averaged one hour and forty minutes, which, I believe is less than is usually seen in a similar group of priminars. Certainly the time was not benthened.

Forcests Forcests were used three times. Of the two low forcests cases, one was the brow de hvery just mentioned. In the other they were used to terminate labor after the head had been on the perineum one hour. In a third, mid forcests were resorted to because the fatal heart had dropped to noo. This last case had received nitrous-conde-oxygen during the pains for thirty minutes only. It does not seem then, that the need for forcests in any one of these cases could be attributed to the amentation.

be attributed to the ansethetic.

Lacardians: Careful records were kept even
the first degree lacerations, small skin or mucous
tears were noted. These were present in to
cases. In the 20 cases there were only three
second degree lacerations, each one of which was
to be expected under the conditions present.
The first was in the mid-forceps case already
described the second had a contracted outlet
and in the third, the head was born unstituded.

Parisess. The perines in the 30 cases were watched carefully for complications attendent upon the injection of novocaine and quantu area. No abscesses, along his, areas of reduces or inflictation occurred. In a few cases, there was some orderne and considerable tenderness on the second and third day but apparently no more than in other cases in which it was not used. Those perinces that had to be repaired healed promptly

Perisal sujetions: There is no doubt in my mind that the novocaine did improve the relaxation. The perincum is a large field to be thoroughly injected, but the distribution of these large quantities of solution is materially aided by the pressure of the head against the muscles. The quint meal in the quantities used was apparently of little service in relieving

the screness after delivery but it may have aided in keeping up the local aniesthesis in the more protracted cases.

Babies All but two of the babies in the 20 cases were born slive pink, and in excellent condition breathing spontaneously One was stillborn at about eight months. No foetal heart had been heard for several days. In the other case the mother a III para had been sent in from the Out-notient Department because the fortal heart had gone up to 170. The cervix was stenosed mid forceps had to be applied and the child was born with the cord tightly coiled about its neck. Nitrous-oxyde-oxygen had been given for only tifteen minutes, followed by ether for one hour This child could not be resuscitated and death was plainly due to suffocation on account of delay in delivery. In neither of these cases, then, can death be attributed to the nitronsorade-orveen.

CONCLUSIONS

I In conclusion I with to emphasize that this experience, brief as it is in accordance with that accumulating rapidly on all sides today that nitrous-oxide-overn analgesia is safe to both mother and child.

2 The use of limited amounts of scopolamine during the first stage is a distinct advantage, shortening the time during which gas is required and making the analgema more complete

3 The work done to far has encouraged me in the bellef that the nijection of the perneum is a distinct help in securing relaxation of the couler. This point spaned, gas-oxygen me experienced hands will do as well as either chloroform or other. The lack of any complication whatoever resulting from the perineal injections should encourage those who feel timed about its unfail about its un.

4. The combined use of scopolamine nitrousoxide-oxygen, and local infiltration offers a practical and efficient means of conducting labor and extends association in its broadest sense to the observation field.

In closing it is a pleasant duty to thank Dr Breitstein for the generous and open minded way in which he gave me access to material at the University of California Hospital. I wish also to thank Drs. Seaver and Gelston for their valuable help in carrying out this work.

PERINEAL ANAISTHESIA IN LABOR

BY ROBERT W KING M D DENVLR C L RICH

HILE marked advancement has been made in the realm of anæsthesia as applied to the local and general blocking of the sensory nerves of various parts of the body it is strange that so hitle attention has been paid to applying these methods to the sensor, innervation of the female perneum—especially since the agitation of twilight sleep has engaged the attention of profession and latty. The literature of this subject is remarkable because of its scarcity the subject apparently has not engaged the attention of American investigators and practically the only work of importance that hy come to my notice has been carried on in Germany.

What work has been done has been directed toward the blocking of the pudic nerve but this has not received the attention it deserves

The pain of the dilatation of the cervic is not of the same intensity as that suffered by the birth of the head, and seldom requires an eitheria of any sort. The suffering caused by the advancing presentation on the perineum has been attributed to the stretching of the soft parts, and this pain is always more severe in primipara than in multipars.

A further knowledge or understanding of the sensory innervation of the temale penneum and the part played by Colles fascia in the production of pain in childbirth will modify this view and a better understanding of the anatomy of the part will lead to better success in attempting to block the nerves.

By blocking the pudic nerve in the ischiorectal fossa there will be a fair degree of anæsthesia of the anterior triangle and perfect ancesthesia of the posterior The anæsthesia of the anterior portion will not be perfect because part of its sensation is derived from the inferior pudendal genitocrural and the inguinal nerves (Fig. 1) that do not enter the posterior triangle. The major portion of the pain in the second stage of labor is due to the stret hing and rupture of Colles fascia which is more sensitive than the integument of the part and which also varies in density and elasticity in different subjects. As Colles' fascia is always more or less torn in the primipara and not so frequently or to so great an extent in multipara it is readily seen why the suffering is more intense in the former than in the latter

Anatomically Colles fascia corresponds to the

Interal extension of the hymen and like that structure it possesses great sensibility to pain. If this point i fully understood and the sensory paths and fascial planes (Fig. 2 and 3) are studied in the illustrations it will be possible for the general practitioner to safely and easily block the sensory innervation and deliver the patient painlessly or at least with a minimum degree of pain rendering the employment of other anaestheties unnecessary.

My former objection to blocking the nerve in the ischiprectal fossa has been because of the low vitality of this fat filled space and the possible danger of puncturing the pudic artery

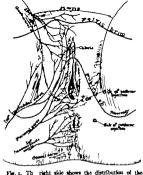

Inhitration of the first has not been followed by any adverse circumstances however and I am now blocking the nerve of both the anterior and posterior triangles of the parineum in women who have given birth to a number of children or who present evidence of much laceration of Colles fuscia.

There are many apparent advantages of this method over the administration of general or spinal anasthesia in childbirth or genecologic operations which make it very desirable that it should receive a thorough trial in chines having suitable material.

I have had much difficulty in working out the innervation and fascial planes as here given owing to the lack of soutable material in the dissecting room and the fact that the published works on anatomy that I have had access to have with one exception dismissed this important part by referring the student to the male analogies. The later works on obstetrics and gynecology have also shown an unexpected lact of knowledge of this subject due perhaps to the supposed un importance of an intimate knowledge of the fumale perneum to the general practitioner.

ANATOM'S

The pearshaped pace of the perincum is divided into an anterior and position ritinangle I via a transverse line passing between the tube rosities of the ischium indivariable tween the annual variana. The lateral angles of the anitor riperties are the results in different suljects and the full arch must be carefully palpated and the first injection chosen in reference to the particular patient. The anterior transple cananal full sensors increase in the first patient and the first patient and the first patient and the first patient and the first patient and the first patient and the first patient and the first patient and the first patient and the first patient and the first patient and the first patient and the first patient and the first patient and the first patient and the first patient patient and the first patient patient and the first patient pa

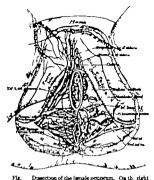

sensory nerves of the female perineum. The left skie shows the landmarks and alto t enter the needle in blocking these perves in labor or periscal operations.

The posterior triangle contains the sensory nerves of the region to the coccyx, the anus. Colles' fascia and the triangular ligament, and a part of the periphery of the anterior triangle.

The superficial fascia of the Fascial planes anterior triangle consists of two layers the peripheral layer contains fat and varies m thick ness in different women (Fig. 3) it is continued over the posterior triangle forming a meshwork containing the fat of the ischiorectal fossa. The second or superior layer of the superficial fascia of the anterior triangle is Colles fascia and is an aponeurotic membrane which is very sensitive to pain. Passing forward this layer is represented by Scarpa's fascia of the abdomen and the suspensory ligament of the clitons. Across the vaginal orifice it is represented by the sensitive hymen. Posteriorly it is reflected behind the transverse perineal muscles and blends with the two layers of the triangular ligament and the perineal body, laterally Colles fascia is attached to the rams of the pubic arch. This fascia forms the floor of the superficial permeal interspace the roof being the inferior layer of the trian

gular ligament. The deep perincal fascia is the urogenital dia phragm or triangular ligament. It also consists

ide Colles' fascia is removed showing the sensory innervation and blood supply of the superficial perineal interspace and achievectal region. On the left ada Colles fascia is reflected showing the entitleder both and stand and the inferior layer of the trungular figurement cut to show the artery of the bulb in the deep permeal interspace. In the ischiorectal fosts the anal fascia is removed and the space cleared showing the location of the pudic vessels and perves.

of two layers that become continuous behind. blending with the permeal body and Colles' Anteriorly these layers are senorate. laterally and anteriorly both layers are attached to the pubic arch and between them is altuated the deep perineal interspace

A study of these fascial planes demonstrates the ease by which the spaces may be infiltrated and the contained structures subjected to the influence of the solution for a considerable time, owing to the impervious nature of the fascin and their attachments when intact making it impossible for the solution to escape except anteriorly from the superficial interspace beneath Colles faacza.

The perineal spaces The superficial interspace contains all of the sensory nerves of the anterior triangle except a few fibers of the genitocrural and illo-inguinal nerves. It also contains the principal vessels, the superficial muscles, and the vestibular bulb and gland (Bartholin's gland) the location of which must be remembered or failure may result if injection is made into them

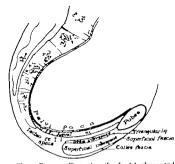

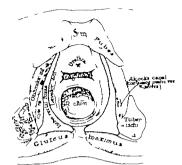

Fig : Diagram illustrating the fascial planes and spaces governing the extent of the anesthetic infiltration Note the anterior projection of the achierectal space.

The deep perineal interspace contains no nerves necessary to block in labor the dorsal nerve of the chtoris which enters this space leaves it and passes into the anterior portion of the superficial interspace

The ischiorectal fossa is generally stated as being situated in the posterior triangle but reference to Figs 3 and 4 will show that there is an anterior projection between the levator ani and the superior layer of the triangular ligament passing nearly to the symphysis The solution will readily infiltrate the loose tissue of the space but it is necessary to use a greater amount than in the anterior injection. Alcock s canal, which is a sheath formed by the obturator fascial contains the pudic nerves and vessels supplying nearly all the structures of the permeum. The situation of this structure about 4 centimeters above the margin of the tuberosity marks the depth to msert the needle for the injection. Care must be used not to make the injection into the obturator muscle or the dissipation of the solution may prevent sufficient anasthesia of the perineum. If the solution is injected into the fossa it will have effect upon the permeal nerve and also the hæmorrhoidal and sacral nerves giving sensation to the structures of the posterior triangle

TECHNIQUE

Prepare a 2 per cent solution of novocaine in normal saline sterilize it by boiling allow it to cool and add 15 of a minim of 1 1000 solution of adrenalin chloride to each cubic centimeter

Fg. 4 Diagram illustrating th canal and the antenor projection of the ischiorectal forsa.

eltin of Alocks

- 2 Palpate the pubic arch to be sure of the landmarks
- Wash the site of each injection with alcohol or benzin followed by the official functure of jodine A Spray each site lightly with ethyl chloride before entering the needle
- . In the anterior triangle enter the needle 2 to 4 centimeter, above the lower margin of the vagina and 2 centimeters from the rami. Pass the needle to 4 centumeters in depth, corresponding to the level of the hymen or its remains and the expression of sudden pain as the needle meets the positive resistence of Colles fascia will indicate the proper depth pass the needle through the fascia and inject the solution the anterior triangle use 11/2 cubic centimeters of the 2 per cent solution for each injection
- 6 In the posterior triangle incline the needle laterally and enter it midway between the anus and tuberosities to a depth of 4 centimeters the posterior triangle use from 5 to 10 cubic centimeters of a r per cent solution in each injection. Varying as to the adiposity of the subject
 - The injections are made bilaterally
- 8 Primipara require only the anterior injection
- Multipara may require both anterior and posterior injections

SUMMARY

No adverse results have followed nearly 100 injections A slight superficial necrosis of the inner lips of the labium has followed the injection of stronger solutions of adrenalm but this in all

- cases cleared without harm

 2 Ansesthesia begins in a few minutes and is
- prolonged two to four hours
 3. Laceratons are diminished in number and
 extent for the consciousness without pain of the
 patient allows retardation or advancement of the
 presenting part at will, thereby developing the
 fullest elasticity rowable.
 - 4. Harmorrhage from lacerations is greatly

diminished due to the adrenalin and lessened

- 5 Repair is greatly facilitated because of the
- 6 Benzin or alcohol and iodine sterilization of the obstetric area can be rapidly and painlessly carried out under this procedure when the posterior triangle is infiltrated.

The general practitioner can safely and easily apply the method at the ball-ide

AN OPERATION FOR BACKWARD AND DOWNWARD DISPLACEMENTS OF THE UTERUS

B IOHN M ALLEN M.D. F.A.C.S. St. IOMOGRUPY VERNONT

THE operation described below has been performed fourtent times during the past treelve months and has given so uniformly good results in all these cares that the writer deems it worthy of report. The fourteen patients of the varying degrees of beckward and downward displacements of the uterus from simple retroversion to complete prolapse. Th ages ranged from 25 years to 64 years. In most of the cases repair of the perice outlet as well as attention to the cervix user lawls because in under the contract of the cases required the perice outlet as well as attention to the cervix user lawls because in under our law of the cases required the perice outlet as well as attention to the cervix user lawls because in under our law of the cases of the cases required to the perice outlet as well as attention to the cervix user lawls because in under our law of the cases of th

larged, or greatly elongated it was amputated by the circular method, which measure of course lightened the lead markedly.

lightened the load markedly. The abdomen is opened in the midline by a four inch incision the lower limit of which is about one and one half inches above the symple sia publis. The skin and fast are pushed back from the edges for one half inch throughout the whole length of the incision and any work spon the adners or lower abdominal contents is carried out. Holding the edge of the rectus sheath taut

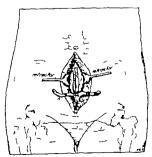

Fig. z. First step. Two parallel strips A cut from the rectus sheath.

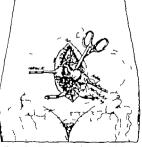

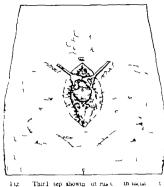

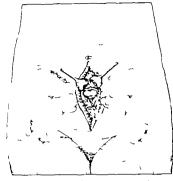

Fig. a. Second step, showing forceps pushed through broad legiment just below round legiment, from behind forward and on through peritoneum, posterior rectus sheath and fibers of rectus mucks, ready to group and of strip.

nd trap. 4 ready t be sewed in cross inicial a post rair surface i uterus between uterface ends i round I gament a trap of this about one fourth of an inch wide

is cut from the margin as long as the incision The upper end is severed and the lower end i left attached. The uterus is next brought up high enough to make the posterior surface ea v of access as low as the origin of the round liga ments and a shallow cut is made across this surface from the origin of one round ligament to the same point upon the other ide. In making this cut the knite is held at an angle to the uterus of forty ave degrees so that later on the inculion may be completely closed. The uterus is then drawn to one side and held firmly while the next important step is taken In eight inch hæmostat with laws curved to a right angle with the blade 1, thrust from behind forward through the broad ligament on a level with the end of the incision on the posterior surface of the uterus and made to traverse the following structures in the order named the parietal peritoneum and posterior rectus heath the nbers of the rectus Thence it is made to emerge at the edge of the wound with ut having pierced the anterior sheath of the rectu- and at or near the level of the lower end of the incision in this latter structure. The ian of the hæmostat are then opened and the free end of the trip of the rectus sheath previously cut is graped and the hæmostat i withdrawn until the jaws appear at the point where they entered ie at the end of the groove in the uterine wall just below the round

1 4 F unth tep in the operation in the terms in the pening with the strips wexted in the incision and to ach other

The same procedure is carried out heament upon the opposite ide the ends of the strips are cut to proper length if too long and they are then utured carefully to the bottom of the groove with twenty-day gut The ends may be made to meet in the midline of the uterine wall or may overlap. The cut in the uterus is then utured with time gut and one or two stitches are made to include the strip the round ligament and the broad ligament on either side The uterus will then be seen to be in most excellent position hanging free and unattached to other tructures and no raw urface for adhesions will be tound other than the mall area upon the two small strips of aponeurotic tissue, which is almost negligible in amount

The chief advantage claimed for the operation is that the new support is made of the use which will not stretch out in a few months after active life has been resumed. Uso the uteru is made one of two links of a chain which will held the varianal walls in place. Better anatomic position is ecured and maintained than in many of the other varieties of operations for the relief of these conditions.

All patient so far have been completely relieved of the di-tressing sympt in complainted of prior to operation. It is it course ob noise that this method can only be used in patients past the menopause or in others where the tubes he ebeen used or other means of sterilization employed.

SPONTANEOUS EVOLUTION IN SHOULDER PRESENTATIONS

WITH REPORT OF A CASE

By RALPH M. CARTER, A.R. M.D. GREEN BAY WINCOMEN

TEPHENSON in a recent article, states that spontaneous evolution in transverse presentations has been observed only twice in 13,000 consecutive labors at the Johns Hopkins bospital, and all authorities agree that it is a very unusual occurrence. On account of its rarity therefore, a report of the following case may be of interest.

On February 27 g 6 I was called to attend Mrs. K living eleven miles in the country I found woman 34, five feet six inches in beight and well developed. Sixe informed me that she had passed through five previous labors, all normal and not particularly difficult. Pains in the present labor began about 5 p.m., and the bag of waters ruptured about 8 p.m., followed abortly by the prolapse of an arm. Hard pains then ceased, except for an occasional one. A midwif was in attendance, but with the prolapse of the arm, she rightly decided that the case was beyond her skill.

Under conditions as aseptic as possible considering the circumstances, I made an evandoution with light anasthesis, administered by the midwife. I found ecantilo-anterior with prolange of the left arm which as of good color. The cervix was fully dilated, and the nterus closely police to the fortus in the condition of passive contraction. The shoulder was firmly wedged into the pelvis, and it was impossible to get the hand into the uterus to perform version ithout using more force than I cared to employ under the circumstances,

ith absolutely no skilled assistance at hand. As the term was not markedly thinned, there were no hard pains, and the patient' general condition was excellent, I decided to move her to the hospital. She stood the trip in the aut very well, arriving t the hospital at the cod of the eleven mile drive in practicall, the same general condition as ben left her home. She had few pains

condition as ben on reute but they were not hard ones.

A few minutes after her arrival the pains increased markedly both in number and intensity and in short time, she was having violent bearing down pains at intervals of t or three misutes. She was placed immediately on the table, and light other anesthesia administered. The prolapsed arm had now become very much swollen and congrested, and the shoulder had rotated beneath the publs. Almost without pame, spontaneous evolution by the method of Douglas took place. The chest, abdomen, and breech were consecutively forced over the perinsons, followed by the legs and the other arm after which the head was extracted without difficulty The placents followed within five minutes.

The child was dead, but as shown by the changes occur ring in the prolapsed arm, death bad been very recent. It weighed six pounds, and was fully developed. The neck

was markedly clonguted.

The mother made an uneventful recovery and left the hospital on the eleventh day

Transverse presentations are always pathologic. While the above case demonstrates that they sometimes terminate spontaneously yet with very rare exceptions, the children all die and very frequently the mothers, if aid is not given. If left to Nature, several terminations are possible

I Spontaneous rectification may occur. This usually takes place during the last month, and is brought about by the contractions of pregnancy It occasionally occurs during the early part of the first stage. Spontaneous version may be brought about

during the first stage of labor or rarely in the beginning of the second. The head or the breech may come to lie over the inlet, usually the former

3 Spontaneous evolution may take place

4. The pains continue, no advance is possible the uterus ruptures, and the patient dies from hemorrhage or infection.

5 The pains may cease, the feetus be retained and become infected, decomposing and giving rise to a physometra, in which condition general

sepsus and death usually follow

Spontaneous evolution may take place according to one of three methods (1) That of Roederer also known as spontaneous expulsion or evolution corpore conduplicate This is much rarer than ordinary spontaneous evolution, and requires a much roomier pelvas in proportion to the size of the foctus. The shoulder is forced down into the pelvis and the body is bent, bringing the head and thorax into apposition. Both the latter enter the pelvus together and emerge simultaneously from the vulva, following the birth of the shoulder (2) The method of Doug has of which the above case is an illustration In this method, which usually occurs in cases with prolapse of an arm the head is arrested above the inlet, the neck becomes very much elongated, and the chest, abdomen, and breech are forced out alongside the arm, followed by the legs, the other arm, and the head. (1) The method of Denman, which is the rarest of the three. This usually takes place in back posterior positions. The head rotates posteriorly the shoulder ascending simultaneously with the descent of the breech which finally comes down and out. A fourth method, or at least a hitherto undescribed modification of the method of Douglas has recently been observed by Stephen son In his case, the left shoulder with prolapsed arm became fixed beneath the public arch as in Douglas method. Following this the but tocks emerged from the outlet with their anterior surface in contact with the inner surface of the arm. This latter method must be extremely rare and the force required for it to take place is undoubtedly very great.

The above-described mechanisms while they are very interesting in that they demonstrate the marvelous adaptability of the processes of Nature to unusual circumstances occur so rarely in practice that they should never be depended upon

For spontaneous evolution to occur we must have a roomy peivis a small easily molded fectus and very strong pains. It always occurs late in the second stage. Once started however the rapidity with which the process is completed upon by several observers and illustrated in my own case. From the onset of the severe pain to the birth of the placenta the time was lifteen minutes. The total duration of labor was eight hours.

Since it is practically impossible to predict in which cases evolution will take place and since the results of neglected transverse presentations are so serious expectancy in the hope of evolution has no place in the treatment of this class of If seen early in labor a short wait to see if apontaneous rectification or version will occur may be justified. If neither of these takes place version should be performed as soon as conditions Oftentimes deep anæsthesia will will permit allow turning where otherwise it appears im Above all gentleness and care in all manipulations should be the first consideration and if the shoulder is deep in the pelvis, the uterus contracted closely about the child and the latter does not turn easily attempts at version should be abandoned. If the lower uterine see ment is greatly thinned version is contra indicated as a rupture will almost surely occur In these cases decapitation hould be performed In exceptional circumstances when the child is living the woman is in good condition and the surroundings favorable casarean section may be considered

BLOOD TRANSFUSION WITH PARAFFIN-COATED NEEDLES AND TUBES

BY BETH VINCENT M.D. FA.C.S. BOSTON

THE results obtained by the transitison of blood are probably less dependent upon the particular method employed than upon any other factor pertaining to the subject. The indications for a transitison and the selection of the donor are more important than the technique of the operation. The therapeutic value of the blood is the same whether transferred by the citrate method as described by Weil' and Lewi sohn! with the glass cylinders of Kimpton and Brown! the pipet-cannula apparatus of Satterlee and Hooker! or by the syringe method of Lindeman! For this reason each surgeon should familianze himself with the method which suits his own needs. The following method has been

Neil Richard J Ans M Am. 9 5, kny 4 5 Les nohn Surg Cynec & Obst. 9 5 km, 27 kmpton and Brown J Am M Am. 9 5 July Satterine and Hooker J Am M Am. 9 6 Teb 26 Lindeman Am J Obst. N. Y 923, vt. 8. useful to me and may meet the requirements of other operators

For the past three years I have used a glass tube or flask with a paraffin costing which inhibits the congulation of blood and allows ample time to transfer it from donor to recipient. The tube resembles in principle and differs in shape from the cylinders described by Kimpton and Brown and the pipet of Satterlee and Hooker. This method is easy and practical but requires a skin incision to expose the vein in both donor and recipient which is not necessary in many cases.

Recently I have modified the tube so that it can be used with a needle of special design which obviates the skin incision on individuals with suitable veins. After a veirs experience with the needle and tube at the Massachusetts General Hospital and in my private work I find that this

-attacles and Hooker Surg Oynec, & Obst 14, 224, 35

is the case with the donor at least, in a large per centage of transferences

The tube (as shown in Fig. 1) is a cylinder with a capacity of 900 cubic centimeters the upper end of which is closed with a rubber cock. About 3 centimeters below the end is a side opening where connection is made with a bulb syringe which is used to express the contents of the tube. The lower end of the cylinder terminates in a glass tip through which the blood enters and leaves the tube. About 3 centimeters above the end of the tip is a ground glass Joint by means of which a tight connection can be made with the

The needle is 6 centimeters long and consists of a shaft and a socket of about equal length. The socket which is the special feature of the needle, is made of an unusual depth so that there is no contact between the needle and that portion of the glass tip which projects into the socket below the ground glass joint. The needle is made in two sizes, number 12 and 16 gauge. I find that I use the larver size in most cases.

PRIPARATION OF TUBE AND MELDLE

The tubes are cleaned with hot water wrapped in a towel with the cork and a short piece of rubber tubing and sterilized and dared in the autockave. The process of coating the tubes with parafin is then carried out under aspelle conditions. I have used §4 parafin and varsous mutures of stering parafin and varsous may but find that a commercial strike sold under the name of "parowax serves all practical purposes."

The paraffin which has been inclied and steril incel in a metal dish is aspirated into the lower end of the tube and the outlets are covered with past of gauze while the tube a turned to make the wax run over all the inner surface. The excess of paraffin is allowed to run out at the tip leaving a small amount in the tube to cover the cork when the tube is placed upon end to cool. This forms a disc of wax which makes the cork artight, a condition which is essential to the proper use of the tube. As the tube cools a conting of paraffin appears on the linear surface. One should make sure that this covering is uniform and that the outlets are patent before the tubes are done up in sterile towels and put saids for future use.

The needles are cleansed, dired, and heated until sterile in a dish of melted parafilm. With sterile forceps a needle is then taken from the dish and the excess of war is removed by shaking or by blowing air through the needle with a bulb syringe during the process of cooling to preven the formation of a ping of wax in the lumen. The

needles are then sterile and coated and can be kept in a sterile box until needed

This process of coating the tubes and needles requires some practice and is bothersome to the surgeon. It is one of the disadvantages of the method but the work can be delegated to any intelligent nurse. Prepared and put up in this way the needles and tubes may be kept Indennitely and are always ready for immediate use.

USE OF NEEDLE AND TUBE

The method of using the needle and tube anes with the case to be transfused and the experience of the operator. The tube should be used without the needle in cases in which the veins of both donor and recipient are small or hidden by a heavy layer of subcutaneous fat or when the surgeon lacks practice in ein-puncture and is unable to enter the vein without causing a hæmatoma. Under these circumstances it is advasable to expose and open the vein through a skin increson and insert the tip of the tube directly into the vein as described by Kimpton and Brown. The blood is usually taken from one of the larger years in the donor's elbow, while any vein in the arm or leg which will admit the glass tip can be used in transferring the blood to the recipient

In most transfusions the veins of the donor are large and easy to puncture with the needle while the veins of an animic recipient are apt to be small and hard to locate. For this reason it is usually ad inable to take the blood from the donor into the tube by means of the needle then disconnect the needle from the tube and highest the blood into the recipient through the glass tip which is inserted directly into a small vein previously exposed by skin inaction.

Figure 3 shows the manner of using the needle and tube to take the blood from a vein at the donor a chow. The arm is prepared with iodine and a small amount of novocan is injected into the akin over the selected vein which is made prominent by a tournhypet applied above the elbow. The application of the tourniquet is important it should be placed directly on the skin and adjusted by the operator so as to secure the maximum venous tension without stopping the atternal flow. The needle is connected to the tube before making the puncture and inserted into the vein toward the wrist. As soon as the vein is entered the blood opposan at the bottom

of the tube and steadily rises to the top by virtue

of the pressure in the vem The rate of flow is

increased if the donor works the fist during the

procedure. When the tube is filled, which

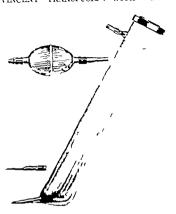

Fig Coated glass t be with needle and bulb ringe

usually takes three or four minutes the flow is checked by releating the tournique. This should be done before the needle is removed to avoid the formation of a hamatoma. As the needle still attached to the tube is withdrawn pressure is made over the vein at the site of puncture. The needle is then disconnected from the tube and rinsed in rold salt solution. During thit time the tube is kept in a horizontal position with the tip up to prevent the escape of blood. To complete the transfer place the higher over the upper opening of the tube to control the flow of blood depress the lower end and insert the tip into the vein of the recipient.

Figure 3 shows a tube half filled with blood which is being injected by this technique into the internal suphenous vein just above the ankle

The average transfu. on requires at least 600 cubic centimeters of blood. In most cases if a hematoma does not form around the vent it is possible to take two and sometimes three tubes of blood from the same vent by reinserting the needle through the original skin puncture. It is not necessary to use a fresh tube and needle for each transfer of blood. If clean-ed immediately with cold salt solution they may be employed a second or even a third time in the same transfusion. A single tube and two needles usually

I.g. Show use f needle to take blood from vein at the elbow

uffice for a transfusion although one should always be prepared with at least two coated tubes and extra needles

The combination of needle puncture for the donor and inci, ion for recipient is the practical method in most transfusion but under certain circumstances it is possible to use the needle on both the donor and the recipient. In such cales after the tube has been filled with blood from the donor as already described a needle is inserted into the median basilic or median cephalic vein of the recipient made prominent by a tourniquet above the elbow. A soon a blood if we from the needle the tourniquet is loc-ened the tube filled with blood is a needle with the needle and the content expressed by means of the syringe.

This needle and tube method without inci ion applies especially well to the infant with an open anterior fontanelle where the blood i injected into the superior longitudinal sinus a suggested by Helmholz.

Helmholz H.F. Van J.Obet 1 1 1

Fig. 3. Show technique of inserting glass up int. weln which has been exposed and opened through skin incision. Position of tube to inject blood int. internal suphenous yein.

In my last seven cases of hemorrhanic disease of the newborn I have employed this method with very satisfactory results. The blood is taken by means of the needle from an elbow vein of the father who usually serves as the donor One half a tube or 150 cubic centimeters of blood is sufficient as the amount required to transfuse these cases varies from 90 to 120 cubic centimeters. The infant is placed at the end of a table with the head on one side, as shown in Fig. ure 4, and held firmly in this position by an assistant. The needle is inserted at the posterior angle of the anterior fontanelle exactly in line with the sagittal suture. The sinus is just beneath the skin and dura and large enough at this point to be located easily even in a newborn infant. As soon as the needle enters the sinus the fact is revealed by the flow of blood from the outer end. The needle is then held firmly in place while connection is made with the tube and the blood is slowly injected. The blood must be injected slowly to avoid a too rapid increase of intracranial pressure. In two of my cases this caused vorniting and disturbed respiration which corrected itself as soon as the flow of blood was

Fig 4 Show position of mfant head and point t high th injection of blood is mad t the longitudinal sinus

checked temporarily. Air pressure in the tube should be released by detaching the syringe before the needle is withdrawn. There is no bleeding of any amount from the sinus even if the puncture has been made with a fairty large needle.

The ched dusad antage of this method of transtismon lies in the preparation of the needles and tubes but this process is not difficult and may be done in ad ance. The costed needles and tubes can be kept indefinitely and are always reads for immediate use. In practice the method is certain and Seafule. The combination of needle and tube allows the surgeon to make a choice of procedures to suit his own operat: e experience and the need of the individual case. The tube with open incision is a sure method for any transtission and under favorable conditions the use of the needle with the tube materially simplifies the operation.

TRANSPLANTATION OF THE ABDUCTOR HALLUCIS TENDON IN THE SURGICAL TREATMENT FOR HALLUX VALGUS

B JOSEPH E FULD M D N w YORK

Instructor in Operator. Surpery College of Physicians and Surpeaus, Columbia Lancerety. Associant Vanding Surpeau, Gottoment Hospital

AN operation for hallux raigus must have in view (1) the correction of the deformity (2) the prevention of recurrence (3) the preservation of the longitudinal arch

The usual operation of the resection of the head of the metatarsal bone meets only the first requirement. To meet the second requirement

I devised and found feasible a transplantation of the tendion of the abductor hallucis from its usual insertion in the plantar surface of the base of the first phalanz to the personetum covering the middle of the inner surface of the same bone. To meet the third requirement, I have confined the bone section to the canotions, when possible,

Fig. Showing bony projection 1 B Li of extrasion

without resection of the head and follow this by suture of the capsule over the denuded bone area deep to the transplanted abductor tendon to prevent involvement of the transplanted tendon in the sub-sequent and inevitable callus

The histories of a moderately large number of cases treated by this operation show that it will be rarely necessary to resect the head of the metatarsal bone.

After a thorough trial of the various operative methods this operation has given me the best results. The simplicity case and safety with which it can be performed in my opinion warrant its trial in these cases. It allows the patient to walk well and absolutely without pain the great toe remains in perfect position and is naturally mobile, and it does not affect the weight bearing function of the foot.

TECHNIQUE

The steps of the operation are as follows

I Under general anæsthesia forcibly move the great toe in all directions stretching the contracted tissues.

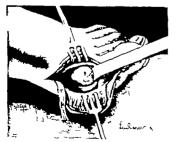

Fig. 3 B Bony projection T tendon of abd ctorhallucis C capsule.

. Fig. () Caps le T tend n of beduet r hallucis to transplanted

- 2 Paint the foot and toes with iodine
- 3 Make a slightly curved incision about two inches long beginning one halt inch in front of the bony prominence on the inner side of the great toe. A semicircular flap of skin and subcutane ous inssue is dissected free from the bursa and turned down over the joint so that the subsequent scar will not be at a point of pressure (Fig. 1).
- 4 The soft parts are retracted. The tendon of the abductor hallucis is now seen under the head of the metatarsal bone and is dissected free from its attachment to the base of the first phalanx (Fig. 2).
- 5 A flap is now made including the bursa capsular ligament and periosteum and turned down exposing the bony deformity to view (Fig. 3)
- 6 Apply the chisel to the bone at the junction of the condyle and globular head of the meta

AN IMPROVED SUBSTITUTE FOR IODIZED CATGUT SUTURES

II BACTERIOLOGICAL TESTS

BY CASSIUS II WATSON BY M.D. BR LENY

I ha previous communication (1) the author reported certain experiments which demon strated that a double salt of iodine—potas-aum mercunc iodide—potas-sed marked advantages over iodine for the impregnation of catgut sutures. Briefly the results were as follows.

I Potassium mercunc iodide in waters and alcoholic solutions possesses more than ten times the germicidal efficiency of iodine

2 Sutures impregnated with this double salt have a tensile trength 6 5 per cent greater than plain sutures and 10 5 per cent greater than iodized sutures.

3 Sutures impregnated with the double salt when sealed in tubes containing a suitable storing medium—show no deterioration when the tubes are subjected to boiling water.

The substitution of potassium mercure codied for odine seemed to constitute such a distinct improvement in the preparation of antiseptic stuties that it was deemed desirable to develop a method for thus impregnating suture materials and then to subject such products to e.haustive lacterological tests. The experiments reported below were planned to determine—

- r The efficacy f the procedure in producing sterile sutures and
- 2 The degree of anti-eptic or germicidal powers imparted to such sutures by their impregnation with potassium mercuric iodide

To this end therefore raw dehydrated catgut sutures were treated with an alcoholic solution of this salt placed in tubes with variou storing fluids and the tubes sealed. Heat sterilization was omitted in order to make the conditions of the test more exacting. All tests were controlled with samples of plain chromic and iodized catgut from several reliable manufacturers.

IL STERRILITY TESTS

Exterioral Technique The tubes containing the sutures ere immersed for one hour in warm bichloride of mercury solution (... 200) drained free from the solution. broken the suture removed with sterile forcers, washed quickly and thoroughly in so com stenie water the adherent water roughly removed by draining the suture against the inner surface of the container and then immediately placed in tubes containing 75 cens of nutrient broth. Duplicates ere planted in summar tubes of broth covered with thick layer of sterile liquid paradin t issure anaerobic conditions. All tubes were incubated for seven days at 17 5 C At the end of that time, if no ventile growth had appeared, as further control agar slant were inoculated with portions of the broth in which the enture had been incubated. Twelve tubes each i lots

and were tested Result All tubes showed absence of growth, and sub-inoculation of the broth on agar proved their sterlity Sutures of both plain and chromic cateut impregnated with potassium mercuric lodide ere not tubed, but instead were preserved in paper cavelopes. They were subjected to no heat sterilization, and further

no preta tions were taken in handling them t present bacterial contamin tion. Twelve sutures were tested as in Experiment

Result. All remained sterile.

Experiment 3. I order t determine whether the absence of growth in the broth in Experiments and was due t the actual terflity of the autures or to the inbibliting action of the impregnating substances on bacteria already in the gut the strands from ten of each of the incubated broth tubes of sutures and moved under aneptic precautions, washed again in ter

and planted in fresh tubes containing 75 ccm. of broth. Reserved I no case was there growth.

The outcome of Experiments 1 2 and 3 would seem to attest the efficiency of the method for impring the complete sterihention of the suture materials.

COMPARATIVE BACTERIOSTATIC EFFICACY TIT. OF SUTURES IMPRIGNATED WITH IODINE AND WITH POTASSIUM MERCURIC IODIDE

Experiment 4. T elve tubes from lots. A and B and A and B and four tubes each of all the other lots ere first tested for sterility by the method described above After seven days inculation all ere found t be sterile.

To each tube was then added ccm. of 24 hour

To each tube was then added broth culture of virulent and actively growing strain of staphylococcus pyogenes aureus. Table I shows the remilt after further incubation of seven days.

In none of the tubes containing sutures. I said B and al and B was there growth, while only one tube of lot of showed freedom from infection. The inhibiting power of the entures impregnated ith potassium mercuric lodiciwas marked.

Experiment & I order t determine bether the inhibition of growth in the tubes containing sutures and 9 was due t an antaceptic or germicidal action the

following test as made From all tubes each of lots A and B and aA and B which had been inoculated with staphylococcus from

at tubes rack of lots 1.1 and B and 1 and B inorniated with becallus gabtiles, and from one tube of I t q all hich had show no growth on inculation (Experiments and 5) 5 and come of the broth as piretted

cem of the broth as pipetted 4 #Ed 5) in 15 ccm. of fresh broth. The purpose was t dil to the possible content of impregnating substance divolved from the suture in the first broth tube and by this dilution t do

y with any purely inhibiting action. If growth occurred, it ould then show that the suture powered merely antiseptic properties while, if no growth occurred

it would indicate that the catgut contained a sufficient amount of the impregnating substance not only to inhibit but actually to kill the organisms. The result is shown in Table III

I periment tures of l to 1 and 1 w re washed tertile w t pl ed in deep petri dishes the co ered with fl id par which had been inoculated with taphy locorus aureus and the plates in ubated.

τR

2λ

В

It was felt that such an experiment would in the first place approximate in wire the conditions existing about a suture planted in human tissues further it would demonstrate to what degree impregnating substances diffuse through such a medium and to what extent an antiseptic or germicidal zone is thus created

Figures 1 and 2 show in a striking way the marked inhibitory power of catgut impregnated with potassium mercuric iodide as compared with iodized catgut. The lighter areas about the imbedded sutures represent zones of no bacterial growth while the darker portions in the plates are masses of staphylococcus colonies. It should further be remembered as has been shown in Experiment 6 that in the case of the former sutures the inhibiting action is truly germicidal while in the case of lodized sutures the action at most is only antiseptic. It seems particularly significant that the potassium mercune indide can diffuse and exert an inhibitory action to such an extent through a medium as dense as agar Iodine on the other hand has only a slight diffusibility

If this experiment can be considered as a criterion of the conditions obtaining about a suture

imbedded in human tissues it is evident that catgut sutures impregnated with potassium mercune todide protect the tissues against bacterial infection to a much greater degree than do the usual todized sutures.

DISCUSSION

Experiments 1 and 2 demonstrate that the process of impregnating catgut sutures with notassium mercuric iodide renders them sterile and the efficacy of the method is attested by Experiment 3 which shows that even when such sutures are preserved and handled with entire neglect of aseptic precautions they remain sterile In Experiments 3, 4, and 5 the results prove that sutures impregnated with potassium mercuric nodide have sufficient inhibitory power to prevent the growth of staphylococcus pyogenes aureus and even of the sporulating bacillus subtilis while the ordinary indized sutures have little or no such action (one suture out of 64 inhibited both the staphylococcus and bacullus subtile, but failed to kill them) Experiment 6 shows fur her that this inhibiting action of potassium mercunc iodide is not merely bacteriostatic but is truly germicidal

CONCLUSIONS

- 1 Potassium mercuric iodide is an improve ment over iodine for the impregnation of suture materials in so far as their physical properties are concerned (1)
- 2 Sutures impregnated with potassium mer cunc rodide possess a decidedly greater inhibiting power on the growth of bacteria than do sutures impregnated in the usual way with rodine
- 3 The inhibiting action of potassium mercuric iodide sutures is a germicidal one

REGULAR MERITOG HILD FRIDAY EVENING, APRIL 21 1916 WITH THE PRESIDENT DR. CHANNING W BARRETT IN THE CHAIR

EXTERNAL INCOMPLETE RUPTURE OF THE UTERUS FOLLOWING SUBPERITONEAL HEMORRHAGE

Dr. A. J Written (Augustana Hospital, service of Dr. R. W. Holmes)

On February 7 9 6 at 1 15 p.m. Mrs. A. H. was admitted to Augustana Hospital in labo The patient was married, 35 years of age, mother of six children, the oldest being 6 years and young est 434 years. Each birth had been normal and easy Labor was due February 17 1016 as the The patient did not know when she concel ed when life was felt. From the history obtained it would neem she had had no seem the history obtained it would neem she had had no seem the history obtained it would neem the had been she had had no seem the had been seem to be highly seem to be had been seem to be had been seem to be had been seem to be had been seem to be highly seem to be had been seem to be patient had menstruated last on May would seem she had had no trouble during the pregnancy On February 6 at 3 pm. the nations went into labor At 2 30 a.m. the following morning physician was called and fou d the head floating membranes intact, and slight amount of dilatation. At 2 30 p.m. the sam day the head was fixed, with complete dilatation, and the membranes intact which were then ruptured artificially At 5 o clock the occiput was to the right and the head low Without anesthesia forceps were t tempted several times, but without success in lock ing the instrument. As the patient had not been prepared on admission to the hospital she was taken care of at the hospital by the nurse in the delivery room. The patient was catheterized, but only a few drops of bloody urine was obtained. Labor was strong and the pulse was 114 at 10.45 p.m after the preparation was completed. Five minims of pitu itrin was given hypodermatically and contracti as became active diastasis of recti muscles was very marked. At 10 to the pulse was 132. Five minims more of pituitrin was given hypodermatically and at 11205 o clock a female child weighing 8 pounds 14 ounces was born spontaneously At placenta was expressed by Crede.

At 11720 the patient had a pulse of 40 and respiration of 33 and was fairly comfortable. Sometim siter midnight she woulded a large amount of yellow floid. Proctocypis of 500 could camilmeters of normal salt-solution was given at 3 a.m. and again at 6 a.m. and all was absorbed. The patient did very well and at 53, m., the first day of the poetpectum (February 28) the patient was given an ounce of oleum fichilo na excount of dyspocas.

from excessive tympany and an enema the following morning with good results. At p.m. the find by f the puerperium (T bruary 8) the patient was catheterized. As the patient had voided 4 ounces t to 50 m the catheterized urine was cloudy speedif gravity roz it was acid, albumin was present t gram per litter leucocytes t hydline casts, granular casts and some amorphus urates were found.

On the second day of the puerpersum (February g) at 4 p m the patient had a temperature of o pulse of 8 and respirat one of 8 no chest findings. There was considerable tympany but the patient tated that h always had this with each puerperal period and that she usually got relief with oleum ricini. From that time o patient had fever involuntary bowel-moveme t and was not doing well About midnight (March) the patient vom ited a great deal of coffee-ground fluid, but after gastric lavage sh felt quit comfortable. The following morning she complained of severe abdomunal pains and omited great deal of clear fluid The temperature was pulse thready weak, and of poor volume Respirations were 4 At 4 p.m. the fourth day of the puerperium (March s) the temperature was 104 pulse 140 repirations 36 and there were involuntary boardmovements. During the afternoon of March : and morning of March 4, the patient had involun tary urination but was quit comfortable. Tem perature oo pulse and respirations 18 at 4

About 8 a.m. on the fourth day of March, the fifth day of the purperium, the patient suddenly collapsed, the pulse became thready and weak and of low volume, recorded as 60 at 8 50 vomited coffee-ground material, became pulselers, and died at 6 of that morning

Post-mortem examination of her pelvic viscers was permitted and this was performed by Dr. Karl Lewis. The shdomen was distended, and on opening the peritoneum, an almost explosive gush of blood escaped from the incision, running over onto the floor. I see 'ver fresh addicatos were present. The uterus was hardly involuted. The peritoneum separated from the uterus from within the left broad raried from the uterus from within the left broad broad ligament. The bladder was expanted total broad ligament. The bladder was expanted to the viginal statements. In the uterine well under

the left broad ligament an incomplete external rupture was found. This was probably due to a rupture of an intramural blood vessel with a development of a subperstoneal hamatoma, which when dissected separated the loosely adherent pentoneum of the anterior uterine wall and the bladder and ruptured enteroabdominally on the fifth day of the puerperium

The baby was born with asphyxia pallida and was revived with difficulty. The child did not breath well for 10 to 15 minutes and oxygen was administered The following morning it died respirations becoming slower and slower The child

had several convulsions

Dr. RUDOLPH W HOLMES On admission this patient was exceedingly tympanitic, which con tinued until her death. She stated she always had this tympany with each puerperium. The question arose had the uterus been bruised by the for cens attempts was the infury due to prolonged pressure of the lower segment against the pelvic brim or was it due to stretching of the lower segment that is a threatened runture of the uterus account of the tympany this could not be deter mined In a cursory review of the literature I find the report of a case in the service of the Boston Lying in Hospital some ten years back which pre sented a rupture of a sinus postenorly in the lower segment. The patient died of an intraperitoneal himmorrhage. We know that vessels rupture oc casionally into the broad ligament producing a broad ligament hematoma.

A MEMBER When do you think the rupture occurred?

Dr. Holmes Unquestionably during labor or at least shortly post partum Unquestionably an interstitual intramuscular harmatoma formed with in the cavity found in the uterine wall under the antenor fold of the left broad ligament Later under the influence of the mild pentonitis and metri tis, the wall broke externally after an extensive dissecting hematoma had raised the loosely ad herent perstoneum and bladder and on the fifth day the peritoneum ruptured. It may not be questioned that the hematomatous sac ruptured at 8 30 a m. when her collapse came.

A MEMBER How do you account for the blood which was present in the bladder when she entered the hospital?

Dr Holmes Hamatuna is not infrequently found in labor especially obstructed labor due to pressure congestion with minute apoplexies of the vesical murous membrane and rupture

A MEMBER Il as the bladder separated from the uterus?

Dr Hollies From the appearance of the speci men the primary rupture occurred at the left broad hgament at which point there was a distinct cavity which almost extended down to the uterine mucosa-The loosely adherent peritoneum of the anterior uterine surface was stripped off from the left to the right broad ligament. Likewise the entire bladder

was separated from the uterus down to the attach ment to the vagina. It was as completely accomplished as it would have been in a total hysterec tomy

PERITHELIOMA AND ENDOTHELIOMA OF THE DTERUS

Dr W A Newman Dorland read a paper en titled Perithelioma and Endothelioma of the Herus.

A CRITICAL REVIEW OF THE LITERATURE PER TAINING TO THE RELATION BETWEEN GYNECOLOGY AND NEUROLOGY

Dr Richard R Smith Grand Rapids Michigan read a paper entitled A Critical Review of the Literature Pertaining to the Relation between Gynecology and Neurology 1

THE LEUCOCYTES IN PREGNANCY LABOR AND THE PHERPERIUM

DR JOSEPH L BAER read a paper (by invitation) entitled The Leucocytes in Pregnancy Labor and Puerperium. (See p 507)

DISCUSSION

DR CHARLES S BACOY I think the tables given will be very interesting for study when one can look them over a little more carefully than has been possable here

I have been in the habit of making a routine count generally on the first or second day after labor simply for the purpose of comparing that with a subsequent count that would be made in case of any rise in temperature. We have found always a rather high leucocytosis, about agreeing with that given in the tables tonight. The difference in the reports of various authors have been so great that I had about given up any hope of making any use of the leucocyte count in general in determining the prognosis of the case in any respect whatever I regard this as the best collection of cases certainly the best work that I know anything about and I believe that we will make use of it in the future

Dr. Gilbert Fitz Patrick In order to check up some of these findings we carried on some in vestigations in our own clinic. We made use of Bier's pump during lactation, and after having used the pump on several occasions in comparing the count we found where the pump had been used rythmically at nursing and then making a count shortly afterward there was a slight tendency toward an increase of the lymphocytes

A CONTRIBUTION TO THE ETIOLOGICAL STUDY OF OVARITIS

Dr. CARL HENRY DAVIS (by invitation) read a paper on A Contribution to the Etiological Study of Ovantis (See p 560)

Published to I terast. Abs Sers

DISCUSSION

Dr. C. S. Bacox Without attempting to discuss this paper I would like to ask one or two questions. I understood that the author assumed that fibrocystic degeneration and ovaritis are synonymous terms. I do not know exactly why I understand that it is assumed that bacteds cause the fibrocystic degeneration. I do not know why To prove that ovarian injection must be hematogenous two cases were given where there was no connection between the varing and the overy. In one of those cases, however there had been an abdominal opera tion with drainage, and of course that would furn ish a mode of entrance for the bacteria into the ovary. In the other case there was no such possibility but I suppose there was the poughflity of an infection by the lymphatic route

Although these objections do not by any means show that there is not a hemotogenous injection of the ovary and I suppose all must adout its posalbility still in the establishment of a positive pathogenesis and carrying it so far as to suggest the treatment of local infections as local foc for the prevention and cure of infection in other parts of the body it is necessary or desirable at least to absol tely eliminat other methods of infection.

Dr. N SPROAT HEAMEY Experience shows that a blood borne infectio can cause nelvic inflamma tion, as witness the occasional suppurations with be cillus typhosus of ovarian cysts in the course of typhoid lever. I have had one ordinary pelvic abscess which developed during a typhoid fever and yielded the bacillus typhosus in pure culture Dr Davis cases with blocking of the lower passages through malformations of development and chronic inflam matory changes in the absence of a history of acute disease absolutely show that also chronic pelvilesions may result from infectio brought through the blood stream. A w, since other departments of medicine and surgery through the work instituted by Rosenow show daily convincing evidences of the production of chronic inflammatory processes in various oceans as a result of a chronic distant focus it does not seem strange to me that the sam may be tru of the pelvis as is true of other fields.

It m w be a question as to whether this work of Dr Davis is co clusive in this particular point that chronic cystic disease of the ovaries results from blood borne atreptococcus viridans infection from distant fock

Dr. Mark Goldstine What has always bus aled must a case of chronic ovaritis where one opens the abd men and finds both varies affected is which ne of the overles will be sterile, which one will give trouble later on, and which one is infected by th streptococcus vindans? If we leave the overy the patient comes back with sympt ms worse than the symptoms f th artificial menopause because sh has had severe operation and till has the pal sh complained of before th operation and pati t wh has been operated upon and has not been cured f her symptoms is not satisfied

I w uld like to have Dr D vis explain how we can tell when both arres seem drseased, which one is sterile and which

Dr Da is (closing the discussion) While the possibility f a lymphatic infection in these cases has t be taken int consideration the experimental work which has been carried out and which you can read in the J wand of the American Medical Association April 15 0 6 I think gives pretty strong evidence of the hematogenous origin. So far as telling which overy to leave and which one to take out I do not know y more bout how to choose between them now than I did two or three vears ago I have studied and gon over carefully the symptoms which are given by the patient studied the pathological andings as ecorded by the operator I have studied the "aries as seen under the microscope and I do t know anything more about how to choose betwee them n w than I did three or four years ago So that when I am operating on a case I keep i mind and have the nurse re read to me the carefully recorded history of th sympt ms and if I find two overses with apparently not much choice between them, in a young woman, and her pain has all been on the right side. I make it a practice t leave the left ovary If her pain has been on the left side I make it a prac tice t leave the right ovary

CORRESPONDENCE

To the Editor I find that through an error in copying the manuscript for Dr Murphy's article on Bone and Joint Disease in Relation to Typhold which appears in the August imue of SURGERY GYMPCOLOGY AND OBSTETRICS, credit was not given to D Charles M Jacobs for certain paragraphs taken from his excellent article Spon

taneous Luxation of the Hip-Joint as a Sequel of Typhoid Fever, which was published in the April 10 4 issue of the American Journal of Orthopedic Surgery We greatly regret this unfortunate error and wish to say that it was an unintentional over sight that Dr Jacobe' name was omitted.

D MATTHIAS, Secretary to the late Dr. Murphy

BOOK REVIEWS

A CRITIQUE OF NEW BOOKS IN SURGERY

BY MAJOR G SEELIG M D St Louis

FOR several months past there have appeared omparatively few books devoted to the technical side of surgery Recently by contrast the tech nical side has been emphasized again and this month we have three volumes devoted almost unqualifiedly to the Simon pure art side of surgery Of course a coincidence of this sort - and it is a mere coincidence -calls for no comment. The activities of men as individuals and as groups always show a tenden "v to manifest themselves in waves. There is this of interest however in the three volumes under consideration namely that each embraces a differ ent field of technique thus driving home the lesson that even the so-called carpentry side of surgery demands for its mastery a fairly wide acquaintance ship with an ever broadening field of activity a field broadening with such rapidity and such in evitableness that specialization is being for ed upon us willy nilly not only by the demands of an academic grasp of fundamentals but also by the requirements of specialized technical procedures We shall probably revert to this later in the review For the time being it is only necessary to point out that one of the three books is a hardy perennial on general technique-an operative surgery written by a master and appearing now in its seventh edition another deals solely with the technique of the administration of angesthetics and finally the last one is devoted to technical procedures on the upper air passages.

As a whole the three treatises are clear cut con cise, and admirably specific both in their purpose and in the way they set about to accomplish it This is saying much, for as a rule the average description of a simple operative procedure is mildly maddening I have often thought that much of the travel side of surgery - the peripatetic meander ings to the clinics of other men - owes its origin to the fact that the descriptive art of surgical writ ing is so feebly developed. Men want to see for themselves that which the cold and unresponsive printed page falls to drive into their consciousness. In furnishing a tentative explanation of these sur gical wanderings I am of course not deprecating them for they are truly among the best things in the life of a surgeon. The point is that men find difficulty in describing a complicated act on paper The following quotation selected from the writings of a humorist is apropos and illustrates the point to perfection. A friend writes to the humorist inquiring how to the a bow the and tractical the following answer. You hold the the in your left hand and the ollar in the other. Ship your neck in the collar and cross the left hand and relight the right end with the other hand. Then drop both hands catching the left with the right and the other with the other. Reverse hands and pick up the loose ends with the nearest hand. Pull this end through the loop with your unengaged hand and squeeze. You will find the knot all the dand all you have to do is to untangle your hands.

WHEN one finds himself face to face with a heavy tome like this seventh edition of Binnie's class sical work he covertly prays for the gift of conden sation. Very recently a critic demonstrated this gift by reviewing Binnie & Operation Surecryin remarkably small compass driving home his opinion in the fol lowing short introductors sentence. In the dozen years Binnie a Operative Surgery has been before the profession it has grown steadily in size and im portance until it has become as nearly indispensable a reference work as such a book can be affirmative and well intonated. Amen, to the above expression of opinion would constitute an a lequate book review in this instance for those who know their Binnie demand no critique and those who do not know him ought surely to have acquaintanceship forced upon them by the information that he is indispensable

Convention demands however more than a recommendation to purchase. It therefore becomes necessary to point out that the ex-eith edition like its predecessor appears in one volume form—bulky and full but manageable with perfect comfort. In common with all the previous editions, this one sets up as its aim the constant endeavor to give aid to the surgeon when he is in trouble. One fact alone furnishes assurance that the aim has been accurate and that fact is the large number of mea who in past years have expressed their dependence upon this book.

The general management of the parts remains as heretofore There are evidences scattered through out the whole volume of emendations and deletions and there is a notable addition of quite a number

M at or Oversative Stratter By John Fairburn Brane AM CM + ACA, 7th ed., revised and enlarged. Philipdelphia P Blibbles Aca, 516.

of new cuts that illustrate the text admirably Several of these cuts are from remarkably recent current literature. In all, three new chapters have been added o e on cardiac surgery a abort one of nearly three pages on retroperitoneal neoplasms, and an appendix on war surgery written by Dr Walter S Sutton. This chapter by Dr Sutton, although it is particularly well done considering the exigency of space, seems to mirror the tendency of the times rather than to possess any large inherent surgical value. This ordnion, however may be faulty owing to the fact that supersaturated as we all are with surgical war reports written as arience

we are very apt to sniff at a resume of thirty pages. There is practically nothing of consequence in the field of operative surgery that one cannot find in this volume. Furthermore, when he finds it, it is described, without exception, in the most onmistakable fashion. There are no bow tie fiascos lying around loose. If one were forced to point out defects he could only mention several bits of evidence of careless proof-reading, and possibly suggest that Dr Binnie, for safety's aske, should point out more clearly the dangers inherent in the various proposed methods of curing hydrocele by the injection of todine carbolic acid, and other irritant chemicals. In a book of this sort more space ought not be devoted to instilling caution than to describing methods of introducing potential agents of gangrene into closed cavities.

But after all has been said the final fact remains that the book comes about as near being a surgical bible as anything non-biblical can.

THIS next book limits itself to the technique of ancesthesis. Practically everyone who will first read the preface carefully and then go through the text, will reach the conclusion that this volume is in a class by itself. It has been said by someone that good writing depends most largely upon proper thinking. Here is a book that seems to have been thought out well in advance of writing it. There definiteness of arrangement, a clearness of exposition and a critical selection of data that makes it serve exactly the purpose that the author had in mind namely a ground work upon which the student interne, and general practitioner may ac quire a more comprehensive knowledge of the art of enesthesia. I know of no other text that I would so gladly place in hands of junior internes indeed, the great body of internes have been waiting for a practical treatise of just this sort.

Of course it is true that one lays down the book, after going through the three hundred odd pages without a new concept of the theory of anesthesis, of the literature of the subject, or of the underlying physiology or physiological chemistry of the lecithin bodies but if one cavils at this, it is because he failed to read the preface, and therefore missed the purpose of the work. Flagg's object is distinctly the art as contrasted with the science of angethesia: and it is art with a large A, for nowhere in the text does one find a scintilla of evidence of polemic adherence to any special technique of administration. Nothing Flagg very wisely says should be

permitted to dominate over the art in the broader The technical principles underlying the use of angathetics serve as the keynote in every chapter

And these chapters are deverly arranged so as to be very inclusive without being burdensome to the beginner Part I, mad up of thirteen chapters. is devoted to general anasthesia, local anasthesia and mixed sparsthesia. Under general anasthesia. discussion of complete and incomplete there is (rausch) general angesthesis, a detailed discussion of the ind ction and maintenance of and recovery from general annisthesia, the signs of angesthesia. their elemificance and interpretation, ether by the oral, pharyngesi and intratracheal insuffiction methods ethyl chlorid chloroform, and finally nitrous oxide alone and in combinations with oxygen and ether Each ansesthetic is dealt with under the headings. General Considerations and

Technique of Administration, and always in the most eminently practical fashion. Carefully select ed illustrations do much toward clarifying the text. The twelve pages devoted to local anaesthesin are necessarily totally inadequat and we believe the author could have left them out to advantage merely confining himself to volatile angesthetics Local anesthesis has grown to dimensions far and away beyond small compass even when skilinily condensed by Flagg. Of ourse, such a change of

title would have cut out the chapter on mixed an esthesia, but till we think it would have been worth while. By mixed anesthesia. Flagg means spinal anesthesia. Heretofore the phrase mixed aniestheda has referred to compounds such as the A. C. E. mixture or to mixed local and general amenthesia. We wonder whether Flagg has not introduced an element of confusion in changing the nomendature.

Part II is devoted to F ctors Incidental to the Actual Adminstration of the Anasthetic, and discusses preliminary medication, post-operative treat ment duties of the nurse, before, during, and after angethesis, rehreathing emergency angethesis. amenthetist a records, aspirators, and finally a closing chapter on The Point of View of the Patient. This final chapter on The Point of View of the Patient is, in its way a classic. It breathes a spirit that one rarely encounters in a medical book, and ought to be issued in leastet form and taught catechism fashion to every anesthetist be be embryonic or full fledged.

THIS next volume is the one referred to earlier in this review as forcing upon us the conviction that even from the purely technical side we are grad-

PERCHAL EMOREST TO LARTHMAN STRAINT, By Chevalled Jackson, M.D. R. Laust, The Latyngrossys Company 513

nally being forced into more limited surgical special ization The development of specialties within specialties and the gradual conquest of the more maccessible cavities of the body to surgical approach have been very interesting phenomena in the history of medicine. Nowhere perhaps is this evolution more antly illustrated than in the field of laryngology From Bozzini's first attempts to explore the human larynx by means of his crude laryngeal speculum and Garcia a subsequent perfection and practical employment of the laryngoscope until the achievements of the present day the march of progress may be said to have followed instrumental and mechanical inventive genius The simple Garcia laryngoscope had its limitations for the more inaccessible parts of the larvnx could not be examined with it introduction of suspension larvingoscopy and bron choscopy by Killian and by Bruenings marked an epoch in laryngeal surgery rendering possible the employment of surgical m asures in the deeper parts of the tracheobronchial tree The efforts of Jackson have still further developed this held of laryngology so that today endoscopy and laryngeal surgery constitute a special held in themselves

Until within comparatively recent years lung surgery through the bronch and the removal of foreign bodies from these parts was practically un known Jackson by his instrumental innovations his high degree of technical skill and by the repeated demonstrations of his method upon the profession has so simplified the technique of this comparatively new and difficult branch of surgery that he has placed it within the reach of the surgeon of average skill. In considering therefore Professor Jackson's Peerod Endoscopy and Larynged Surgery it must be remembered that this field owes its advancement and its present technical des elop-

ment to the ingenuity of the author himself The work is not a textbook in the general accepta tion of the term. It is an exhaustive reference work that unquestionably occupies the premier rank in this field. The volume consisting of 705 pages, is not connied solely to bronchoscopy and cesopha It deals fully with the surgical conditions of the tracheobronchial tree and the ersophagus. Symptoms and diagnosis are omitted except in so far as they are necessary for the elucidation of the endoacopic text The essential aim of the author has been to devote his subject matter to the technical aspects of endoscopy and laryngeal surgery and their associated operative problems. The author is quite candid in the discussion of his results and in order that bronchoscopy like any other depart ment of science shall profit by its failures he gives (pages 318-32) the histories of some of his unsuc

cessful cases of bronchoscopy and points out the reasons for the unavoidable lack of success. The book is divided into two parts. The second part is devoted to larvingeal surgery taking up the consuderation of Tracheotomy Intubational Dilatation of Laryingeal Stenosis etc. and is intended for the already experienced surgery. The same may be said to apply to part one

Although Jackson is an enthusiastic advocate of direct laryngoscopy he nevertheless makes it a rule whence is such examination is possible to examine erry case by the indirect method first except in

infants and in urgent cases in adults

What will appeal to the reader is the orderly arrangement of the work and the thoroughness with which details usually skimped are discussed. Thus the subjects of instruments (the author show ung preference of course for those of his own in vention or modification and with which he has obtained the best results) anneathests, source of light introduction of the desophagoscope etc. are taken up separately and in minutest detail.

That the acquiring of skill in bronchearcopy especially in the extraction of foreign bodies means traveling over an exceedingly rocky road may be judged from the author's dictum that no one should think of attempting for the first time to remove a foreign body from a human being until he has at least 100 times removed a foreign body from a dog And areain. Endless patience is an essential

The greatest percentage of su cesses will accrue to him who is so constituted to work calmit and deberated; yet quickly and accurately under severe stress of prolonged work with one eye where a mistake or lack of promptises or accuracy may mean the death of the patient

The chapters on Foreign Bodies in the Larvnx and Trachea. Mechanical Problems of Foreign Body Extraction (Esophagoscopy for Foreign Bodies Bronchoscopy in Diseales of the Trachea and Bronchi Diseases of the Esophagus (the latter comprising 89 pages) are all exhaustive treatises on their respective topics and reflect Dr Jackson s wide experience and Leenness of observa tion. This brings up another point While other laryngologists may differ with Jackson on some points Dr Jackson's statements bear the stamp of deep conviction resulting from broad experience

The book is profusely and splendedly illustrated and it is safe to predict that when the warning nations in Europe will have resumed their former positions in peaceful science there will be a demand for the translation of the work certainly into German, and perhaps also into other foreign languages.

BOOKS RECEIVED

Books received are acknowledged in this department and such acknowledgment must be regarded as sufficient return for the courtery of the sender. Selections will be made for review in the interests of our readers and as

COLLECTIVE REVIEW

PRESENT STATUS OF ROUND LIGAMENT SHORTENING AS A SURGICAL CURE IN UTERINE DISPLACEMENT

B IDNES A CHALFANT MD FAC PERRE

THERE has e been many rems the praise of correction displaces used the uters during past years. The of these reasons are fightheau never in pite that i franklin H Martin i in 11/4 and that i American Livit These to articles has been treed used in he preparate nor this review.

We have rithred did not his rener and in the person is for main rither abdiminal rishor main rithred monitor in the rabdiminal rishonal but have immediately those in run in his rithred hrament were utilized. For richies the roll runs classification has been ad yield.

- i Ingual
- Intra abd mual f ding
- 4. Fixati n to the anten surface of the uterus
- Fixation to the posterior surface of the uteru
 - fuation to the anten rabdominal mall.

DOTE IL PERITI - LIELL DER TIPE

Alque a 144 fire surrested this peration and performed it in the cackaver and on animals. The filter of that we can find files wo kit the report fall mittee of the French Acad my of Medicine appointed to investigate the peration Alque descript in 56 h technique is as follows.

With the patt at in the horizontal position the uterus replaced the surreon determines the

c urse iP uparts gram nt and selects a print in the middle it at this ham a mon his made a little obliquely to the crural arch and about centimeter in length. It the knife is carned tix is a mali branch the uperposal ep rastric may be cut inhich can be Immody tied. The crural arch exposed an incl. in is made in it a little suggest to its niters and two centimeters in length air avs keeping to the middle part of Poupart's Loament Behind the cellular to ue the exposed there appears a print f deep red c enclosed in a heet of dense cellular tustle this is the round ligament called the utero-in-minal. Picked up with ussue it reeps this cellular envelope is specied and the cod is terzed and drawn ut with careful manipulation

The pert neum pre-enti-of at the ring a delicate main in a made around the cord in the purpose of dividing the cellul inbrusheath which accompanies it and it is treed with the handle of the instrument. Finally, it wentle tention the cord is brough outside—it may be drawn out to the extent of centimeters or the then a threaded needle is parts of the ught the thickness of the cord and is attached down in the lower end of the inclusion. The margins of the wound are reunsied with the studies after which the operation is done in the lame manner upon the oponite side.

When one c n_ider that this operation was proposed seventy ears and the reception accorded to what would toda be rather a minor

operation shows very forcibly the wonderful advances of surgery

After giving an outline of the plan proposed by Alquie, the committee renssured the members

of the Academy by stating

"To this brief description, which will suffice to show the importance of the operative procedure involved your committee wishes to add before going further that it is all pure theory that M Alquid has never performed the operation except upon cadavers, and that he does not seem disposed to employ it in the living subject except in animals. This assurance once given we may proceed with less apprehension in considering his work.

And they finally gave this very qualified approval

The operation (which requires always its duplicate upon the opposite side) not being at all admissible in practice, we have the honor to M. Alquif for having had the prudence not to M. Alquif for having had the prudence not to Practice it upon the it ing subject and that it recognizes that there exists in his work some anatomical considerations within of interest.

In (1882) William Alexander (4) of Liverpool published his article in which he reported three cases. He devised the operation and developed the technique without knowledge of Alquié's work which had been done almost forty years before. His technique is very similar to Alquié's.

The operation is perf rmed by cutting down upon each abdominal ring gathering up the ends of the ligaments treeing each from its nerve and gradually releaving them to patient and cuttious traction from the neighboring itssues until the position of the uterus as ascertained by the niger in the vagina, satisfies the operator. The ligament is then stitched to the tissues around the rung, and the loose ends attached to each other on top of the skim or rolled around two pieces of wood which are fastened together in the middle line.

Adams (5) (1882) of Glasgow had for two years been demonstrating in the anatomical rooms the same procedure but had never performed it on a patient. His technique is practically the same as that described by Alexander

An mosion made over the external inguinal ing and a very careful dissection carried downward expose the pale and straggling fibers of the round learnest as they emerge from the maand take attachment to the dense arealar tissue of the moss veneris. When these fibers are grasped by the forceps on mass and steady traction is made, it is found easily practicable

to draw them freely outward to the extent of one or more inches In the dissection care should be taken to exclude the inguinal nerve for its rupture under traction implies considerable pain. Under the necessary traction the peritoneum does not follow the ligament as it is extraded, but separates and peels off There is therefore little risk of an inguinal hernia resulting and any such apprehension is reduced to a minimum when it is borne in mind that ingrenal bernia does not commonly occur in the female. The incision about two inches in length, should be made obliquely and directed toward the mestal line and this oblique direction will be found to facilitate the search for the ligamentous fibers much better than a vertical opening. The search for the fibers of the ligament must be made cautiously and with much patience and little haste for this is the difficult part of the operation. When fairly exposed clearly traced and notated they should be grasped by broad pointed force-ps - small polyp forceps are very suitable - and follow ing the guidance of the ligaments, the forceps should be thrust well into the inguinal ring and the ligament haid hold of as high as possible. When it begans to yield to the traction it may be pulled out to any desired extent Five or six catgut ligatures passed over and under the ligament will sufficiently ensure its attachment to the surrounding tissues while separate ligatures close the wound excepting at the most dependent part. Antiseptic dressing strict rest in hed and the action of the bowels restrained for a few days by means of opiates, should suffice for the after treatment.

There have been many modifications of the technique of Alquié Meyander Adams. opening of the inguinal canal was advocated by Bompiani (6) Roux (7) Kocher (8), Chalot (9) Gardner (10) Cleveland (11) and Edelohle (12) In an effort to increase the applicability of the operation Goldspohn (11) ad ocated opening the peritoneum at the internal ring and through this opening separating uterine or adnexal adhesions This was also suggested by Fritch (14) Maly (15) and Kroenig (16) Bouleux (17) for the same reason, combined the Alexander operation with a posterior colpotomy Peterson (18) with either a transverse or median incision. Sandberg (19) with a median laparotomy kreutzmann 20) Kuestner (21) Schlemminger (22) Rumpf (23), and Palm (24) with a laparotomy by means of the anchor inclaion of Kuestner Rapin and laparotom, by the Pfannenstiel incision was used by Spacth (25) Frantz (26) Worth (27) and Littauer (28)

FILATION OF BOLVD LIGAMENTS

Duret (29) and Franklin Martin (30) (1896) separate the distal ends of the ligaments from their attachments and bring one across the symphysis above the fasca and the them together

symphysis above the lasten and the them objected.

Abbe (31) (1866) splits the fascan over the canal and after separating the distal end from its attachments uses the loose end as a living suture for the double purpose of closing the canal and faring

the ligament

Impallomen (32) (1912) using the Pfannen stiel incision drills the os pubs from before back ward and passes the free end of the ligament through this opening and sutures it to the ligament in front of the opening A double pointed nail is then driven across the opening

Figurea (33) (1913) splits the canal and draws out a loop of the round ligament. By means of blunt dissection and a ligature carrier this loop is passed upward beneath the external oblique out through the fasca again back and out and sutured. He thus makes three punctures of the

fascia of the external oblique

The advantages of the Alquié Alexander Adams operation are that it does not necessitate opening the abdomen the shortening of the ligaments is in the normal course of the ligaments the strongest portion of the ligament is utilized and it does not interfere with subsequent pregnancy or labor The disadvantages are its limited held on account of the difficulty of determining the absence of utering or adnexal adhesions which contra indicate the operation the danger of subsequent hernin the impossibility of locating and correcting the pathology of other abdominal organs in some cases painful scars and as reported by some operators a rather high percentage of recurrence. The modifications which involve opening the abdomen either by the vaginal or inguinal route have divested the operation of its greatest advantage

Laparotomy by any of the ordinary methods gives opportunity to care for disease particularly of the adnexa or appendix and permits examination of the organs in the upper abdomen. With the abdomen opened it is much easier to shorten the ligaments by some intrapentoneal method that no make additional incisions over the in guinal canals. This type of operation appears to have at the present time a very limited field of usefulness.

VAGINAL OPERATIONS

Wertheim (34) (1896) seems to have been the first to use the round ligament in vaginal operations. He attaches the round ligaments 1 or 2

centimeters from the uterus to the vaginal wall. In one case he shortened the round lightness by doubling them on themselves and suturing them with silk.

Guenther (15) (1806) suspends the uterus by the round ligaments by passing a catgut suture from within the abdominal cavity outward through the anterior abdominal wall and tying the sutures on too of the skin

Kiefer (36) (1866) through the vaginal incision doubles the round ligaments as in Mann's opera

Vineberg (37) (1806) gives his technique which he has used in two cases. After delivering the fundus Vineberg passes a suture on either side embracing the round ligament and a portion of the broad ligament adjacent to the uterus. These sutures are carried through the vaginal flaps below the pubic arch at the side of the pelvis and tied.

Byford (38) (1896) picks up the round ligament as close to the pubic end as possible and sutures it to the uterus above its normal insertion.

This is combined with suture of the fundus of the uterus to the pertoneum covering the upper portion of the bladder.

Goffe (39) (180₂) first delivers the fundus. Then the round ligaments are caught with for ceps at a point as far from the uterus as can be drawn to the site of origin of the ligament. This distance is usually 25 to 3 inches. The intervening ligament is folded into a loop the tip of which is uttached to the ligament distal to the forceps. The point originally caught is then attached to the uterus at the origin of the ligament and the three segments of the ligament sutured together.

Ries (40) (1901) divides the round ligament at its uterine end and separates it from the broad ligament for 4 centimeters. He then tunnels the anterior wall of the uterus with a knife and draws the ends of the round ligaments into this tunnel from either side and fastens them with calgul

Childs (41) (1905) folds the round ligaments upon themselves about as in the Goffe operation and also shortens the sacro-uterine ligaments

Shurman (4) (1913) divides the round ligaments 25 centimeters from the uterus and separates the proximal portion from its broad ligament attachments. This is then sutured to

the upper surface of the anterior vaginal mucosa Vaginal operations on the round ligament are for the average operator not easily performed and have not become popular except in the practice of a few men specially skillful in operating by this route. It is difficult to get an exposure of much of the ligament and they all depend upon the outer or weakest portion of the round ligament. There would also seem to be danger of causing sufficient traumatism during the operation to produce adhesions and bere is no opportunity to examine for and correct the pathology to other abdominal organs. Operations of this type have a limited field in obese patients in whom a laparotomy is undesirable and possibly in those for whom extensive plastic operations are required where vaginal shortening of the ligaments would decrease the time of the operation and in this way lessen the risk.

INTRA ABDOMINAL FOLDING

Wylle (43) (1889) series the round ligament at its middle, scarifies the inner surface, and autures the two folds together with the loop to the outer side.

Folk (44) (1883) freshens the inner surface of each round ligament for some little distance along its middle part and sutures the row surfaces of the two ligaments together thus making an anastomous between the bladder and uterus. Ruggi (45) unites a point of the round higament near the internal ring to a point near the uterus with a single catgut stitch. Bode (46) done practically the same thing, but in addition takes a stirch into the comu of the uterus.

Mann (47) (1805) catches the ligament with two forceps dividing it into three equal parts. The point at the outer forceps is sutured under the point where the round ligament is inserted into the uterus. The ligament at the alte of the other forceps is then autured to the outer extremity of the round ligament as it leaves the abdominal wall. In his first operations he used silk-worm gut sutures but later silk or cargut, and finally used several fine catgut stitches along the course of the folded ligament. In this way he has a triple fold of the round ligament.

Jonnesco (48) (1897) freshens the peritoneum at each end of the ligament and autures these two may surfaces and the soles of the loop together with silk. The layer of the broad ligament participating in the fold is then united by means of a suture passed in the form of a U

Morris (49) (1900) makes a small opening in the peritoneum draws out aloop of the round ligament for two or three thicks, sutures the folds of the loop together tucks the loop back into the opening of the peritoneum and closes the open ins. Byford (50) (1003) folds the ligaments to the inner side and sutures the ligament one half inch from the uterine end to a point one-half inch from the uternal ring. The inner edges of the loop are touched with a chemical irritant and then sewed together. The end of this fold is then touched with the irritant and sittled forward and beside the bladder about opposite and a little above the level of the external inguinal ring.

Bissell (51) (1008) splits the round ligament longitudinally into an anterior and posterior portion. The greatest portlom of each half is cut away let align three-quarters of an inch of the distal part of the anterior half and the same amount of the protimal portloms of the posterior half. These stumps are sutured, one to the uterns and the other to the cut end of the corresponding part of the round ligament, then sutured together and the broad ligament repaired. This is just the opposite of the ordinary operation for lengthening tendons.

Pankow (52) (1912) divides the round ligatement at its middle sutures the proximal end over the internal ring and the distall end to the uterus, and then the two loops together

Lorents (53) (107) in his linaugural disserts tion re-kwn the various operations and describes what he terms the N shaped suturing of the round ligament which he states was trut performed by Zaratt. This is very similar to the Mann operation in which the ligament is divided into three equal parts. Two loops are sutured into the internal ring and the other two to the uterus and the three segments beneath the broad ligament in

a groove which has previously been made

The early operations of this type all depending upon seroserous adhesions furnished the greatest number of recurrences, and for that reason have been largely abandoned The later ones in which the edges of the round ligament are freshened or the ligaments resected as in Pankow a or Busell s operations would seem to be difficult to perform and to have no ad antages over the more recent operations of fixation of the round ligaments to the anterior abdommal wall. In addition the operations of this type all fold up or resect the intra-abdominal portion of the ligament which is generally considered to be its stronger portion and depend for support upon the distal or weaker portion. This objection may be more apparent than real. When we consider the cases of re troversion that follow incomplete involution of the uterus and ligaments it would appear that at least in these cases the fault was with the intra-abdominal rather than the extra-abdominal portion of the round brament.

FINATION TO THE ANTERIOR SURFACE OF THE UTERLS

Dudley (54) (1890) denudes an oval area on the anterior surface of the uterus down to the vesical fold of peritoneum and a similar area on the inner surface of the round ligament of each aide. These raw surfaces are then sutured together thus inding the round ligaments to the midling of the anterior surface of the uterus at a point near the bladder.

Menge (55) (1904) catches the ligament near its middle draws it toward the midline and stitches the folds of the ligament together and then the loop across the anterior surface of the uterus on the level of the attachment of the round ligament. The folds of the broad ligament are then attached to the anterior surface of the

uterus.

Coffee (56) (1005) seizes the round ligament with its surrounding peritoneum about one and one half inches from its origin and sutches it by four or five interrupted sutures of catgut to the side and front of the uterus about the insertion of the broad ligament then fastens the next inch and one half of the round ligament back to its original insertion with interrupted catgut sutures. The folds of the round ligament are then covered by bringing the peritoneum of the broad ligament over them with a continuous suture of cat gut

Latzlo (57) (1908) fixes the most external point possible of each round ligament to the middle of the fundus of the uterus forming of the redundant portion a loop on the anterior surface with the convexity down and toward the midline. The inner portions of the two loops are sutured together and to the anterior surface of the uterus. The folds in the broad ligaments are then in turn sutured to the anterior surface of the uterus to close the openings and prevent internal strangulation.

Paudom (58) scarnies the inner surface of the round ligament, folds it up and sutures it to the cornu of the uterus and to the anterior uterine wall at the level of the cornu

Jene (50) dissects the round ligament free for the required distance makes a tunnel in the antenor wall of the uterine cornu one centi meter long draws the loop of the round ligament into this tunnel and sutures it at each end

Willia (60) (1712) brings both round ligaments are to see the front of the uterus and sutures them together and to the anternor surface of the uterus in the middle one half inch below the apex. The folds of the broad ligament are then sutured together and to the anternor surface of the uterus

for a short distance and the suture continued taking up the folds of the broad ligaments only down to a point one half or three fourths of an inch from the bladder 'sperling (61) (1906) Smyls quoted by Ashe (62) (1907) and Stewart (63) (1904) describe operations that are very similar to Menge's

Of these operations the one devised by Coffee (56) has undoubtedly been the most popular in He (64) in a later article gives this country in more detail the principles on which the success of surgical treatment of retrodisplacements He states that the of the uterus depends. support of all the abdominal organs is by folds of peritoneum that the round ligaments are mus cular structures essentially a part of the uterus that muscular tissue has only one function con traction and that under continued strain the muscle will stretch. It is therefore illogical to depend upon the round ligaments for a constant support. In the operation he describes Coffee states that the uterus is supported by the broad ligaments and the round ligaments have time to rest and an opportunity as they are fixed under the peritoneum with catgut to shorten and straighten themselves

Affier (2) ruises the point that an essential for stability of the correction lies in placing the uterus in its normal anteversion. The more the broad figament is tensed and the lower the round ligament is fixed to the anterior surface the greater will be the elevation and anterposition of the uterus and the less the anteversion.

This objection seems to be met by Coffey (65) who in a more recent article reports the conditions found in five patients re-operated upon for other conditions. In all these the broad ligament was found holding the uterus in perfect position. The round ligaments had regained their normal size and their normal position under the pentioneum. In this paper the author reports 272 operations by his method with two known recurrences but apparently, no report had been secured from a number of the patients. Suttner (66) reports 64 cases by the Coffey method with anatomical cure but symptomatic failure in one recurrences in two and one death from conditions having no relation to the ligament operation

Goldspohn (67) objects to Coffet's statement that the pentoneal folds are the true support of the abdominal organs. He claims that the support from the abdominal walls is an important factor as shown by the number of cases of enter optons in patients with relaxed or weak abdominal muscles. The pentoneal attachments of the atterns must become greatly stretched dur

ing pregnancy and once stretched they have no power of contraction. Pregnancy is the true test of operations for retroversion and unless patients are examined after they have passed through one or more pregnancies after the opera tion no concludous can be drawn as to the value of the procedure. The round ligaments are composed largely of non-striated muscle fiber and are a part of the uterus itself and as such they undergo evolution during pregnancy and involution during the puerperium. "The anat omical structure and physiological nature of these ligaments make them a really live and rather intelligent medium for the purposes here Rest will not result in strengthening a muscle this is accomplished by exercise. That rest will not result in shortening the round liga ments is shown by the large number of women who have worn persaries continuously for years with cure in only two per cent.

FIXATION TO POSTERIOR SURFACE OF THE UTTRUS

Menge (68) first used the round ligament as a cover for the pedicles after removing diseased adness, and by fixing the ligaments to the posterior wall of the uterus prevented a recurrence of the displacement.

Stolz (69) draws each round ligament up across the inner end of the corresponding tube and sutures it to the posterior surface of the uterus

with several sutures of silk.

Webster (70) (1901) perforates the broad ligament below the ovarian ligament from behand forward with a hemostat grasps the round ligament and draws the loop through the openingthe round ligament. The loop is then sutured to the posterior surface of the uterus, and the sides of the opening to the round ligament

Baldy (71) (1902) cuts the round ligaments at the uterine end. The free end is then drawn through the broad ligament below the ovarian ligament and attached to the cornu of the uterus on its posterior aspect directly back of the original point of attachment of the normally attached round ligament. The ends of the ligaments may be cut off to secure the proper degree of shorten ing and the point of attachment varied to sunt the requirements of the individual case.

Franke (72) (1909) without knowledge of the work of Webster and Baldy devised a similar operation. In young women, in order to award interference with pregnancy after drawing a down of the round ligament through the broad ligament he fixed it to the ade of the posterior surface of the uterus. In older women the two loops were joined together as well as fixed to the posterior surface of the uterus

Holleman (73) after Franks spaper states that he has been using the method for some time. He suggests that if anteversion is required the opening in the broad ligament should be high, but if elevation is desired the opening should be lower He also sutures the opening in the broad ligament to the round ligament.

Dampies (74) (1910) describes an operation that is very similar to Baldy. The loops of the round hyaments are sutured together behind the tuerus and if it is feared that the sling may slip either up allowing the uterus to drop below or down permitting the uterus to retroller over it, the sling may be attiched to the posterior surface of the uterus with vertical stitches in the central, least vascular portion. Sores (75) (1971) proposes to simplify the technique of the Baldy Webster operation by pulling the round ligament through the broad ligament by the use of an ordinary were harron

Albert (a) (1911) picks up the peritoreum covering the round ligament about 4 or 4 centimeters from the uterus and cuts it with actisors of the ligament. Through this inculion a double loop of atrong ullk is passed under the ligament the ligament is raised a d the peritoricum is stripped bick from it for some distance, most on the distal portion. Two ligatures are made a contimeter apart on the ligament and it is cut between them. The ends of the ligatures are

left long With a Cleveland ligature carrier the mesosalpanz is perforated about a centimeter from the uterine margin the lighture upon the distal portion of the resected round ligament is grasped and the ligature drawn through the aperture. On the corresponding side of the posterior surface of the fundus a tunnel 2 or 3 centimeters long is made with a lance bistoury in a nearly transverse direction passing from the margin of the uterus near the perforation in the mesosalping almost to the middle line. By means of the ligature the bgament is drawn through this tunnel until the resected end appears at the median end of the tunnel. Two sutures are placed at each end of the tunnel They engage the uterine wall, about a third of the thickness of the ligament, and the overlying fleshy bridge. The central stump of the round ligament is then sutured to the penpheral portion with two silk sutures and the opening in the peritoneum closed

Schmitz (76) (1913) in order to avoid the seroserous adhesions of the Baldy Webster opera

tion which is the weakest kind of intra abdomi nal adhesion suggests a modification which he has performed in a few cases. He makes an opening in the peritoneum over the round ligament 3 or 4 centimeters from the uterus and divides the ligament between ligaturedistal portion of the ligament is then separated from the pentoneum for a hort distance ligature attached to the distal end of the round ligament is then caught with a Barrett ligature carner and carned between the layers of the broad ligament to the posterior urtace of the uterus underneath its peritoneal covering very small perforation is then made in the perstoneum of the uterus in the midline ligatures one from each side are then fied unit ing the two ends of the round ligament latter are then secured to the posterior wall of the uterus by a few interrupted statche of fine chromic catgut The proximal ends of the round ligament are then sutured to the distal end as in Albert 5 operation and the perstoneum clived

The Baldy Webster operation as it is commonly called in this country or the sling operation of the English and French surgeons is now commonly performed according to Baldy 5 1 1 (1906) later technique by sutching the loop of the ligaments together and to the posterior surface of the uterus. One of the most complete reviews of the end results of this operation was that by Polak (8) (1913) He reviewed his results in 400 operations with only 4 not seen either by himself or his assistants after operation. He thus has 3.6 patients from whom to draw conclusions. Polak tound a rather high percentage of complications as lateral version prolapsed and evistic ovaries, sigmoid and intestinal adhesions Relapse occurred in patients and 30 others were wearing pes aries. Polal, concludes that the operation should not be selected for heavy uten with the cervix in the axis of the vagina It succes depends on a small uterus a cervix pointing backward equally developed ligament. and a careful technique

The operations of Albert and Schmitz would seem to be rather difficult and tediou, and liable to at least a part of the complications of the others of this type

FIGATION TO THE ANTERIOR ADDOMINAL WALL OI hausen (9) (1886) hist utilized the round ligament in performing ventrobation. He pa see his suture around the round ligament im mediately beade the uterus and then deeply through the abdominal muscles. This is com-

pleted on each ide with two or three sutures

which are then firmly field and thus not the interus fiself but the part of it next the round and broad ligaments is fixed to the abdominal wall. In view of the subsequent devel pment of ventro-mation it interesting to note that Obhausen states that it; alway advisable wherever possible to limit the peration to those patients whose condition or age preduce the possibility of the xeutrence of a pregnancy.

Dolors, so 180 utured the n und figaments into the lower angle of the abd minal more in In hi later work 1 180 he was careful not to extend hi lines for below a point or centimeter above the smphss. On each led of the median line possite that ports in 5 the linea alba which has been preserved he makes a mall opening through which a loop of the r und ligament? I drawn and nived to the under unlace of the kin.

Ferguson \ 1500 eems to have been the originator i thi type of operation original operati n. made a median incl. i in d iwn to the tascia then a short incision through each rectu. agating the round ligament one inch from the uterus dividing it or ximal to the ligature The proximal end was then drawn up into the wound on each side and anchored to the pen toneum and the anterior sheath by the rectus In his later work in 1100 instead of dividing the round ligament as in his former technique, he used the tab wound and loop as in Gilliam's operation but also closed the opening to the outer ide either by a purse string suture from the stab wound down to the bladder and up to the uterus or by uturing the redundant portion of the round ligament to the anterior abdominal

Giliam (%4) 1000 medined Fergu.on 8 ones nal technique by pulling a loop of the round heament through a stab wound to the ide of the median incision and uturing the loop to the upper surface of the anterior heath in the results

Simpson (8) (1905) describes his technique as follows

- 1 Operations upon the lower genial tract such as curetting repair of cervix penneum etc are often required the uspen 1 h being but a counterpart to the correction of the other abnormalities.
- A median abdominal incision one and one half to three inches long L made just above the symphysis

3 Adhesions to the uteru, are freed and lesions of the adness are given such attent on as they require

4 The wound is held wide men by one

retractor which is drawn straight up, thus making the opening vertical and permitting the operator to look far into the sides of the pelvic cavity.

5 The round ligament is grasped by a delicate forceps one such from its uterme attachment and drawn up to the surface of the wound.

"6 A silk suture is passed through the ligatement at this point in such a way as to encircle about three fourths of its dreumference and to include about an inch of that structure in its

grasp.
7 The needle is taken off and both ends of
the suture are passed through the eye of a carner
8 The peritoneum is incised just below and

In peritoneum is invested unit below aim in front of the round ligament. The carrier is then inserted and passed directly forward immediately beneath the peritoneum of the vestcouterine pouch, to a point on the anterior abdominal wall just above Poupart's ligament and an inch and a half to the side of the median line where it again emerges.

"9. Both ends of the suture are grasped and

the carner is withdrawn.

10 One end of the suture is then threaded
on a sharply curved needle which is passed into
the abdominal wall so as to graup peritoneum,
nuscle and fascia again emerging into the

cavity When the two ends of the suture are tied the lizament is drawn into and along the subpen toneal channel made by the carrier round ligaments having been thus secured the conditions existing are entirely analogous to those of an awning The uterus represents the frame, the round ligaments and autures attached, the cords by which it is raised that part of the abdominal wall caught in the grasp of the suture represents the pulley over which the awning cord runs and finally the peritoneum of the venco-uterine pouch represents the covering of the awning. When the cords are tightened the uterus is raised just as an awning is. The pen toneum is thus folded loosely over the round ligaments and when the sutures are tied the uterus is held in normal anteversion just as truly and securely as the frame of an awning is kept more or less straight up after it has been

Simpson reports three cases in his paper. In the first two instead of burrowing beneath the peritoneum it was caught up along its course.

raised and fastened.

Noble (86) (1903) using the transverse incision through the fascia and a vertical through the recti and peritoneum locates the ligament at the internal ring by blunt dissection from the outer end of the incason and traction on the intra abdominal portion. The peritoneum is then separated from the round ligament to prevent the formation of a funned when the ligament is drawn up. A loop of the ligament is then drawn out on top of the muscles and sutured to the under surface of the fascia and if long enough to the loop from the opposite side.

Monigomery (87) (1904) brings the loop of the round ligament beneath the peritoneum of the broad ligament by a siture around the ligament and a higament by a siture around the ligament and fastens it with catgut to the upper surface of the fascia. In his later papers (88) (1905) and (89) (1906) he advocates the Pfanneratlel in cision

Ill (90) (1903) modified the Gilliam operation by separating the rectus muscle from its anterior sheath percing the rectus and pentoneum drawing out the ligament and suturing it to the mider surface of the forcia

Bardescu (9) (1904) brings the loop of the ligament through the fascia and autures the two loops together

Barrett (a) (1003) make a rectus incuson and puis a hightre around the round ligaments two and one fourth to two and one half inches from the uterus. He then paiss a curved forces between the rectus and it anterior sheath, punctures the peritoneum at the internal ring and draws a loop of the round ligament out by means of the ligature previously placed. This loop is them sutured to the under surface of the fascia

and if long enough the two loops are tied together.

Morns if (sq) (roops) lighten and cuts the ligament close to the internal ring and frees the proof
mal end from it peritoneal covering. This free
ligament is drawn through an opening in the
fawki and peritoneum at the outer margur of
the rectus the uterus a drawn up against the
abdominal wall and the two ligaments are
sutured to the fascia and to each other.

satured to the fascia and to each other

C. H. Minyo (p4) (1000) passes a curved forceps
laterally from the lower angle of the incision
beneath the aponeurous just over the muscle to
the point where the round ligament leaves the
addomen. The point of the instrument then
passes over the pulley of the round ligament and
along its course but beneath the peritoneum to
a point from one and one half to two and one
half inches from the uterine horn where the perl
toneum is penetrated the ligament in grasped
and a loop pulled back through the tunnel. The
loops from each side are then satured together
and to the fascia or if not long enough to pe
forstions in the aponeurous. Simpson (93)

(1011) showed that this could more readily be performed by using a long forceps curved to a right angle which he introduced through a puncture in the fascia one and one half inches to the side of the median incisor.

Dudley (96) (1900) by means of a very heavy needle passes a loop of the round ligament from within the abdominal cavit, through the internal ring and the fasca back through the fasca rectus and peritoneum and sutures it to the peritoneum at the point of entrance and of exit

Campbell (97) (1905) makes a median incision to the peritoneum retracts the muscle makes a transverse incision in the peritoneum on each side at the internal ring draws a loop of the round ligament through this opening and fasters it to the peritoneum and under surface of the

Freund (08) (1006) folds the ligaments on the anterior surface of the uterus and stitches them together with some of the fibers of the utenne muscle to the anterior abdominal wall. (99) (1907) modines Mayo's operation by per forating the peritoneum close to the internal ring instead of at the point where the ligament is caught Peters (100) (1007) describes his opera tion which is the same as that of Simpson in his later paper except that he goes obliquely through the muscle instead of to the internal ring min (101) (1000) punctures the fascia opposite the internal ring catches the ligament one and one halt inches from the uterus draws it out and sutures it to the upper surface of the fascia Branch (102) (1910) modities the Gilliam opera tion by closing the opening to the outer side of the ligament as suggested by Ferguson and Simpson and suturing the loop of the ligament to the under surface of the fascia. Crossen (103) (1010) passes a forceps under the fascia and obliquely through the muscle to a point about one inch from the internal ring where the peritoneum is penetrated and the ligament caught about one and one half inches from the uterus (104) (1010) describes the method he uses which he attributes to Richardson. He divides the ligament at the internal ring punctures the fascia at the linea semilunaris pulls the cut end of liga ment through this opening and sutures it to the upper surface of the fascia pulling the fundus of the uterus against the anterior abdominal wall In addition with the continuous suture which closes the peritoneum of his median incision he catches the wall of the uterus in front of the mid Dicken (103) (1910) modifies the Simpson technique in cases with marked relaxation of the ligament by first suturing a loop of the ligament back to the uterus as in the first step of the Mann operation

Strobell (106) (1912) modifies the Gilliam operation by making an additional short incision over each pubic spine A forceps is passed through this incision just above the pubic bone and obliquely outward the ligament caught and drawn out the slack in the outer segment of the ligament taken up and the loop sutured to the Caballero (107) upper surface of the fascia (1012) describes an operation which he has used since 1002 which seems to be exactly similar to Crossen s Byford (108) (1014) sutures the round ligament at a point one centimeter from the inter nal ring back to the uterine cornu and the edges of the resulting loop together. This loop is then brought forward beneath the peritoneum as in the Mayo operation and attached to the under sur face of the tascia.

Talmey (100) (1006) modifies Olshausen s operation by using two sutures on each side the nearest one encircling the round ligament about 2 centimeters from the uterine cornu mann (110) (1010) gives Bumm's technique of drawing a loop of the ligament through an open ing in the peritoneum on either side of the abdominal incision and fastening it into the muscle Vineberg (111) (1911) modifies slightly the Olshausen technique. He fastens each round ligament to the anterior abdominal wall with two catgut sutures the outer one about 4 centimeters from the uterus and the inner one entirching the round ligament at its insertion into the uterus In addition in many cases he catches the pentoneum of the uterus in front of the midline with a few of the stitches that close the incision in the parietal peritoneum

McArthur (112) (1911) splits the peritoneum on the anterior surface of the round ligament one inch from its uterine end to the internal ring. The raw surface of the ligament is sutured to the panetal peritoneum from the internal ring to within an inch and a half of the median incision Neuhoff (113) (1913) does the same thing except that he does not split the peritoneum of the round ligament.

Neel (114 19316) gives his modification of the technique devised by Kelly He separates the fascia from the rectus muscle 4 centimeters to the side of the inclision passes a silk suture through the muscle and perflomeum picks up the periodeum of the anterior wall to the internal ring and of the round ligament to a point one or two centimeters from the uterine comus where the ligament is plerced the suture being then carried

back through the abdominal wall to the starting point and tied. The first of this type of operations Ferguson s and Gilliam s were devised to avoid the greater objection to ventrouspension, that is, the ha bility to dystoma. The advantages are that it

causes no interference with pregnancy or labor it utilizes the proximal or stronger bart of the liga ment it is comparatively free from recurrence and is quickly and easily performed. After the publication of these papers, the objection was made that as there were two bands across the peritoneal cavity instead of the one in ventrosuspension there was a double danger of internal strangulation. This brought out a number of paners in rather rapid succession in which the writers reported their methods designed to over

come this objection. At the meeting of the Southern Surcical and Gynecological Association Cincinnati in 1002 the papers of Ferguson (83) Simpson (85) and Noble (86) were read. In all of which the principles involved are very similar and were thus summarized by Simpson the lignments are to be beneath the peritoneum, are to be directed forward and the proximal or stronger part of the beament is to be utilized. He stated at that time that the procedure he devised permitted of many modifications to suit the ideas of the different operations. How accurately he foretold the future is shown by the number of modifications devised since that time which differ only in minor details from the previous operations.

Concerning the danger of internal strangula tion Gilliam (115) (1911) stated that he had never seen or heard of this accident following his operation although it had followed many hundreds of operations by many operators. This seems to be just as true today as it was then, as we have been unable to find any cases of obstruction reported But as Simpson (85) pointed out a patient may carry a congenital herms for a great many years without ever being aware of its presence and develop a strangulation when well advanced in life. So it would seem that this objection even though it is only theoretical should be given weight. The retroperitoneal operations can be performed just as easily and with practically no more injury to the patient, and are free from this objection That the results of this form of operation are good is shown by Simpson s (95) results, 97 per cent of anatomical cures. As pointed out by this writer there are three classes of cases in which success of the round ligament operation alone is not likely to he uniformly obtained

When the heaments are very deheate. 2 When the congenital attachment of the bladder is low and that of the sacro-uterine lim

ments is high. when the sacro-uterine ligaments and the

base of the broad ligaments have been very much

stretched giving a decided prolapse. Boxée (116) has repeatedly called attention to the function of the sacro-uterine ligaments 85 an important factor in the maintenance of the uterus in its normal position. Where descensus of the cervix is a part of the retroversion some form of shortening of the sacro-uterine ligaments is necessary and unless this is done the nationt will not be symptomatically cured even if the fundus of the pterus is in its normal position.

The majority of patients requiring correction of their displacements are those in whom it has followed a previous confinement. This points to the necessity of careful supervision of patients after their deli ers to secure proper involution both of the uterus and its lignments. This applies just as forcibly to those patients who have had an operati n as to those who have had no such experience

From this review of the various operations for shortening the round ligaments we would suggest the following as the principles upon which a satis-

factors operation depends It should be outckly and easily performed As the condition requiring operation has of itself no mortality any operation for its correction should involve the least possible risk.

It should have a minimum of recurrences. 3 It should not interfere with subsequent

pregnancy and labor

4 The ligaments should be beneath the peri toneum to avoid the at least theoretical, danger of internal strangulation

5. The proximal or stronger portion of the ligament abould be utilized.

6 The shortened ligament should be directed forward or along the normal course of the round ligament.

It should be intraperitoneal to permit exploration of the adnexe appendix, or other abdommal organs.

8 It should involve the least possible trauma turn to avoid post-operative intestinal adheslons

o It should not overcorrect. If the fundus of the uterus is held in contact with the line of incasion a suspension or fixation is liable to take

It will be necessary to have reports of the end results in a large series of cases before any consensus of opinion will be reached as to the value of the different procedures

GENERAL SURGERY

SURGICAL TECHNIQUE

ANASTHETICS

Pembrey M 5., and Shipway F E. Observations on th Influence of Ansathetics on the Tem perature of the Body Prec Ray Sec Med o 6 ix, Sect. Assathatics

The authors make the following stateme ts in regard to heat elimination and prod cti n but give no experimental evidence or references to support the statements. Deep angathesis sholishes the regulation of both the loss and producti n of heat so that the response of the warm-blooded animals to external beat and cold resembles that seen in cold-blooded animals, a fall of external temperature diminishes, a rise increases the production of heat. It is this fact which complicates the problem. The internal temperature of a patient may show a fall, a ruse, or no change according to the conditions involved during the period of angesthesia. A fall in the rectal temperature from 100 to 97 F is within physiological range when the whole extent of the daily variation in temperature is considered, but in the case of a ansesthetized patient subjected to an operation in a warm theater (72 to 74 F) such a fall may occur within one hour

During abort operations of alight severity the necessity for presentions gainst the loss of heat is not superat for in an addit there is owing to the mass of the body, a reserve of heat which is not rapidly dissipated in a warm theater. In such cases the advantages of warm ether as compared with cold, may not be so apparent. On the other hand, in the case of long operations or an operation upon a patient possessing a low resistance, the difference may be of great translated importance.

W M BOOTHLY

Gley The Inevitable Dangers of Chloroform Narcoria (Sur les dangers inévitables de la chloroformination) Bull Acad de méd Par 9 6 1 vr 608.

In discussing a report recently submitted by Revnier a proposed compository chloroformization for diagnostic purposes in the French army. Gley calls attention to the frevitable caults of chloroform americals which are quite distinct from immediate or late accidents. These inevitable results are I stone of the liver and kidneys as well as alterations in the blood and general metabolism.

The first two are well known. Regarding the

blood, different experiments have demonstrated that it he course and especially at the end of chloroform aneathesia there is neutrophile hypoleucocytosia and some hours later neutrophile hypoleucocytosia and some hours later neutrophile polyma cleona. There is a modification in the form of the red globules and a dimuniti in their number red globules and a dimuniti in their number viduals subjected t aneathered to aneather.

Gley states that research has shown that chlorof rm causes an alteration in the organic exchanges characterized by urinary hyperacidity and an augmentation of urinary blorides and non-ordized sulphur etc. Analysis of th blood shows a notable hyperals accompanied by acctonemia and often

acetonuria

Owing to these effect of chloroform intovication the author thinks that the functioning value of the librer and kidneys should be tested before submitting a patient to the effects of chloroform and particularly when successive aneathesias are contemplated in fact the author thinks that the habitual use of chloroform should be renounced o account of the accidents that follow to use W. A. Bakkraka.

Page II. M Spinal Annathesia. Gay II p. Guz o 6 xxx s

For all ordinary cases inhalation anesthesia is the method of choice, but there remain many cases and in which great advantage is t be gained by the half of use of spinal next thesis by means of which either the whole or the greater part of the shock is do e away with and a more complet muscular relevations is gained. The operations in which this method may be of especial improvators are those for acute

bdominal co ditions, particularly if septic any prolonged bd minal procedure likely t be followed by shock amputati is operation on the bones of the lower extremities and certain gentic-

urinary operations

Seventy cases in which the annathetic was given in the Trendelenburg position are reported, in which position it is better to combing general annathetic with the spinal, the small amount necessary to keep the individual unconscious having little if any undestrable effect on the patient who escapes the discount at 61 ying prone for a long period.

The infection is given with the patient lying on the side immediately after which he is turned on the back and the thighs well flexed. Fifteen minutes after the injection of novocaine and twenty minutes after stoyaine the patient is placed in the Tren deleaburg position. Twelve cases were operated on without any general anisthesia. In the remaining 55 there was periest relaxation in 55 In the three cases of partial failure a deep inhalation.

anxisthesia was necessary. There was no use of interference with respiration and no palient field before re over from the indu el paralist. Nine cases died but analysis shiw that probably in none of these was the spinal anxisthe.ia responsible

SURGERY OF THE HEAD AND NECK

HEAL

Don A Treatment of Head Injuries in a Casualty Clearing Station L L i c 34

The author notes the treatment of 10 cases of head injunes operated upon since the war beggin most of them in a saudity learning tation who have located in France not fair from he trench indiving and the cases came under treatment son after the receipt of the injune Casuality clearing stations are not fully equipped or work. The 1a k vray machines—a x vr important essential in the man agement of head asses. The result given by the author were obtained in the absence of vray evidence and its good as the art the voild naturally have been tarbetter with more implete equipment.

The experience in the present war upholds the rule of early operation in all head case. Trace in motor ambulances is bad for head cases especially in winter. Delay means extension or sepais and sepais is responsible for the large majority of leaths either immediate or remote. External scalp nounds injuries to the cradium dura brain and meninges all require early attention to pte sent sepais and this an beginn with better results be ause earlier where the casuality stations are than later on the line of communications.

The plan followed is to cleanse the scalp of all dirt blood and hair The held of operation should be guarded by lean towels the scalp and wound are next painted with tincture of rodine and the wound is then excised freely leaving a clean-cut edge which is undamaged to the eve If there is obvious injury to the skull trephining should be promptly done A hole three fourths of an inch in diameter is made at the side of the opening or assure and the dura examined. The trephine opening may be enlarged with a rongeur and it there is no blood-clot opening in the dura or other injury nothing more is neces-If the dura is injured it is slit up and spicules of bone or blood-clot are removed. Probing with a probe catheter or anger should be avoided unless definite evidence of the presence of spicules of bone metal, or other foreign body is detected. It goes without saying that pressure from intracrapial blood-clot should be treated in the same way

The flap incision which was extensively used in the beginning of the war and the removal of a big piece of the shull by the de Vilbiss forceps are not suitable methods to use at cleaning stations since

they interiere with tub equent operations that may be feemed in essars

shell wounds at pronitibe tillo eilb brain. The ride buillet with a rail list carried to the brain. The ride buillet with a railet at ober ill wed via base sior other implication. Wen with head bydged buillet hould be removed at hime hospitals where brain pecuals are to be found. It is different in cases where bodged hill traument are uspected. The are much more aptionful or influe sep is and task compiliations so that when possible even at a learing station, the rule is to remove them.

An opportunit to tuft the results of English surgeons who believe in hu₀e scalp flaps and large cranial openings and those of the Fren h surgeons who practice the linear or angle inclinion and small trephine openings is interestingly ommented upon in to or of the latter which is considered far more appropriate in casualty clearing stations where lack of adequate equipment obtains

Indications for operation are (1) the presence of a penetrating wound of the head (1) thriess of patient to stand a general anxisthett (3) the presence of a surgeon with some experience in cranial surgery.

The averag operator can always remove durt from the wound by a clean-cut incusion open the cranium wide enough for the extraction of pieces of bone pressing on the dura or six hing in the brain, to favor drainase of blood or pent up brain débris and to restore pulsation. These essentials in olve but hitle shock they require a minimum of time and they are attended with immediate results. When so treated head injuries are followed by primary healing in most cases and cerebral hernia is the exception.

Though gas intection is rare in head wounds free drainage should be afforded by plenty of drainage tubes inserted wherever drainage is called for even in the brain opening. Imple drainage precludes the possibility of dead tissue persisting in wounds and when deviatalzed tissue is eliminated saprophites like bacillus aerogenes capsulatus can no longer thrive.

After battles only the mild cases should be transred to the rear. The most serious cases should be retained for some time for treatment on the lines mentioned, which will put them in a post ion to bear the ill effects of transport. L. A. L. Gesser. Cushing II. Concerning Operations for the Cranlocerebral Wounds of Modern Warfare. MI Surgers o 6 xxxvIII. 60

Wounds of the head and extremities form a large majority of the total injuries in the present war as shown by recent statistics. It has been clearly proved that specialization in the treatment of wounds in this war is of the greatest value in returning wounded men to active service in a condition of comparative health.

The importance f all cranial wounds, h weve allaht, is emphasized. Roberts found that i series of 40 supposedly minor scalp wounds 4 5

per cent had skull fractures with more or less severe intracranial complications.

The author is strongly opposed to the routine treatment practiced at some first line hospit is, by enlargement of the wound by a crucial incusion, elevation of th depressed fragments etc. and gauze drainage. H cites cases in which the esuits of this treatment have been pastisfactory or worse. He believes that in cases of cranial wounds removal t the base hospital where proper equipment carefully planned operations, aided by the \ ray can be had, is the wisest course. H advises a flap-incision away from the w und, thorough exploration closure of the incision with buried gales sut res. supplemented by cutaneous o es (t be removed on the second day) to insure primary healing with scalp protection f r the denuded dura or brain f drainage is advisable, rubber tussu drains in the distant angles of th I cision bould be used gause never Under this treatment the patient a chances are better even after a delay of several days than with an immediat operation at an ill-equipped first line hospital.

The different types of cranial wounds from projectiles are described a th their characteristic symptoms. An important o is the median tangential gutter wound excived the vertex, I volv ing the lateral expansions of the longitudinal sinus. causing stasis in the large cerebral veins. The sympt me are those of immediat bilateral spastic paraplegia i th severer cases - longit dinal unua syndrome A mild case observed by the thor showed weakness and pasticity of both legs milder cases, even with depressed f cture may recover without operation. In the severer cases, with cortical injury operation should be under taken only under the most f vorable circumstances, the operator being prepared to control harmorrhage from a bleeding sinus by implantati n of raw muscle or vulcanized fibrin fibers ligation t be avoided if possible The same principles apply i the treat ment of posterior wounds involving the occipital lobes and cousing ce tral blindness.

In general, th autho believes that good results follow a primary operation with closure even four or five days after the injury poor results with death from meningitis follow in cases treated t the front in the routine way and packed with gause

HORACE B AREY

Browning, W. Th. Anatomical Cause of the Frequency of Hydrocephalus in Childhood. Med Rec 9 6 levels, 950

In the production of hydrocephalus two complimentary conditions are found secretion and reten tion, both processes normal within limits. Unless there is an bnormal damming back there can be no accumulation and it is this phase that the author especially considers

Many partial a d indirect f ctors have some bear ing on this youthful pot atiality narrower passages, softer tissues, thin bones, metabolic growth-errors, etc B t back of these is n anatomical and mechanical peculiarity which is not ordinarily appreciated.

mechanical standpoint there are three causes of hydrocephalu () versecretion as by a block in the veln of Galen leading to excessive prod ct on of fluid (2) closure of the outlets from the ventricles, as at the f ramen of Munro the iter or the three outlets from the fourth ventrici (3) in terference with the effere is from the subarachnoid apace. The first tw. are relatively rare and may occur at any time of li While the third form may occur t any time flf there is an anatomical netullarity which f von it formation in the early

There are two ge ral classes if these efferents from the subara hord spa one may be called the quadruped or an maltype thoothe the (postnatal) huma type. There may be ddltional minor out lets as along or nial nerves o by direct beorption

through the surround ng tas es.

The animal type of discharge consists of minute bannel or ressel that lead from the pinal subarachnoid space long o a going cryes to the extraspinal tuss es. In nim lathese hannels per sist whereas i the human they exist only up to the time of black

When these raues become losed there is a compensatory process which gradually relieves the situ ti and il we fo more complete drainage of bara h old pare P rebionian bod es arad ually d velop lthough th y do not ppea in large numbers until after the twentieth year. It thus follows that the earlier years of h! re especially suscept bl t hydrocephalus before this compensa tory process he become established dafter the clos to of th animal type of vessels J H Skings,

Vilvandrè, G and Morgan J D Movements of Foreign Bodies in th Brain. 1rck Rediel. & Datrother + 9 τL

The uthors report two cases in which bullets penetrati g the brain subsequently wandered from their oruginal location

I the first case the bullet m ved from the fro tal lobe to the wall of the ventricle in the period of two weeks intervening between examinations.

In the second case the bullet moved from the right parietal lobe outward and downward to the occupital lobe in period of ten days.

Both cases terminated fatally

Keschner M: Large Endothelioma of the Dura Compressing Both Frontal Lobes J 4m M 411 916 1 1 19 3

Keschner herewith reports a rare case of a colored woman aged thirty in whom both frontal lobes of the brain were compressed by a large en foth-thoma of the dura diagnosis being ventued by the puthol ogists report of the necropy. In this case expolitialmos was an early symptom and a post neuritic atrophy resulted within a period of nivemonths in total blindness.

There was an absence of the Babinski reaction but the abdominals were present. The Wasser mann test was negative and the cerebrospinal fluid was under considerable pressure. The exact location of this growth was not easy to determine as the symptoms of cerebellar tumor are closely allied to those of frontal tumors.

The author calls attention to the relative value of early and of late symptoms of brain tumer also to the symptoms of tumor of the corpus callosum He does not believe that mental symptoms occurring in brain tumor are necessarily conduced to frontal

lobe involvement
At autops, the brain measured 1 X 12 X 0 cm
and appeared normal with the exception of the
tumor mass

The tumor was attached to the dura in the center of the olivary process of the sphenoid for the distance of one-fourth of an inch and connected with the brain by a few vascular strands. The microscopical diagnosis was endothelioms.

EMIL C RO ITSIEL.

Priuni P Clinical Considerations of Lesions of the Hypophysis (Considerations climes sobre less as de la lupoteus) Pr suc se de Arg at 1916 il 4

The author discusses acromegaly and hypophy sary dystrophia. He reports three cases with a greater or less degree of hyperpituitarism ie enlargement of the face particularly about the in ferior maxillary region extremities enlarged mac roglosala sexual disturbances characterized by diminution of function or lak of development ocular disturbances lateral or bilateral hemianonsia or complete objuctation The radiograph showed a tumor of the sella turcica in each case. The tumor in the first case that of a man was of long and slow evolution and was diagnosed as a simple adenoma The other two cases which were in females on account of the rapidity of evolution were diagnosed as adenocarcinoma. The rapid increase in these cases caused a hermation of the growth from its habitual cavity with subsequent compression symptoms

In these two causes the disturbances of vision were marked Both of these cases were operated upon by the endonasal method and the tumors weighing respectively 100 gr and 12 gr were removed Both patients died

The author thinks the cases show the necessity

for early diagnosis and treatment as in advanced cases like the above the tumor is large and while aurgued intervention offers the only chance of relief yet it is impossible to completely extincted the tumor by any method now in use. WA BEEN 45

NECK

Barnhill J F Some Essential Points in the Anatomy and Surgery of the Thyroid Glands.

1 m J S t 51 3

Miter a preamble in which he makes a plea that the otolaryngologist should perform the surgery of the head and neck the author proceeds to the subject in han? I he points of paramount importance in the surgery of the thyroid are (1) the large blood supply entering the gland at its upper and lower poles (2) the outer or surgical capsule and the inner or grandular capsule between which the dissection of the gland should be undertaken (3) the parathyroid glands one to eight usually four in number with his lie in the intracapsular space.

The chief dangers of thyroidectomy are the anesthesia hemorrhage and shock suffocation from collapse of the trachea injury to the recurrent largy geal ners and injury to or removal of one or more of the porathyroid glands. Exophitalimic goiter patients are always grave risks due to their tone state. To avoid suffocation from collapse of the trachea a tracheotomy tube should always be at hand to be inserted at the first sign of obstructed restriction.

In the removal of the thyroid gland the author employs the horsehoe incision through the platysma after raising the flaps he makes a vertical incision in the midline and inserts his finger in the intracapsular space between the ribbon muscles and the gland to separate the entire anterior surface of the gland before cutting across the muscles. After the muscles are severed and turned back the blunt dis section by finger is continued from the upper pole to the point where the inferior thyroid artery enters the gland This artery is ligated as near the surg ical capsule as possible. The author lays stress upon the fact that whereas both the inferior thy roid artery and the recurrent laryngeal nerve he in a sheath of their own between the traches and the esophagus the artery alone penetrates the sur gical capsule of the thyroid and gland, and if ligated within that capsul insures the safety of the nerve He never makes a special attempt to isolate the

The inferior thyroid artery also marks the limit of safety. In regard to the posterior parathyroid glands which lie in the connectus clusue close to the entrance of the inf nor thyroid artery. In order to avoid the removal of this important structure the author cuis across the gland what hoe above this point and leaves a small lobule of glind tissu. If sith He believes that the operation of thyroid c tomy for simple got ter bould ha a mortality, no higher than tonsillection in adults exof thindmic.

gotter cases should strays be handled in consults then with a competent internist, and if possible no surgical procedure should be undertaken until the pulse has reached 130 beats per minute. Hemo-casas is an important factor in the safety of all operations and should be especially carefully attended to in gotter operations.

E. Frieder.

Goetsch, E.: Functional Significance of Mitochondria in Toxic Thyroid Adenomata Bull Johns II phins II p 9 6 xxvis, 29

The came of thyroid intorication in individuals who show only the presence of circumscribed denoma has not yet been satisfact thy explained Presure of the tumor on surrounding normal throat causing an expression of normal thyroid secretion into the circulation in excessive mounts has been advocated as the explanat in, as has also the theory that th tumor a foreign body acts as an excitant on normal tissue thus producing increased secretio with its train of torke symptoms. It has long been the experience of surgeous that removal of the donoma is followed by clinical improvement if not by cure. The author has temped to solve this pusaling problem by a close cytological examination of the tissue removed in cases of goil r

A typical case of toxic poier in a middl aged woman is dived in detail. A poter of many years standing after various nervous and physical traumate begin gradually to manifest tod symptoms. At operation a direumscribed feetal adenoma was removed from the right lobe and the istimus. Operation was followed by more less immediate in movement and in one year the patient was practi

cally normal. The usual histological study of the services adenoma showed nothing to account for a hyperactivity of thyroid substance. The cells lading the follides were low cuboidal or even flattened, and nowhere was there infolding of the follides. Colloid was fairly abundant. There was no increase in machine the substantity. The usual histological examination of the colloid of the fairly than the colloid was fairly financies of the colloid was fairly abundant.

The utbor attempted to explain the hyperactivity of this seemingly benign adenoma by a close histological study. If chose a technique which above activity and easily the presence of structures com monly ha was a mitoch adria granular rods or fill aments occurre ig in the cytoplasm of all cells being more abounds to the scripe tages of cell life and diminishing numbers as the ell becomes inactive or control of the control o

mltocho dria.

Applying this theory to the adenoma in question by suitable technique of staining the mitochoodria were dem natrated i greatly increased numbers in the cells (the aden ma applying the hypothesis to adetoomat removed in mitochoodria which were clinically inact we of success in mitochoodria was observed. Frank cases of Basedow a disease were also tuched, and they too showed marked in crease in the mitochoodria in the thyroid gland tissue itself. It would therefore seem probable that the presence of mitochoodria in greatly increased numbers is directly correlated with an overproduction of an theesuse ormal thyroid gland secretion.

SURGERY OF THE CHEST

CHEST WALL AND BREAST

Peck, G. A. The Early Diagnosis of Cancer f the Breast A = J S s r g = 0.6 vx 83

The uthor reviews th recent literature giving in abstract the attitude of various writers toward breast tumors and the symptoms which they regard as valuable in making a diagnosis of these conditions, also the important laboratory tests that have been employed as diagnostic measures.

He makes no claim t originality in the article but gives concise and our ity presentatio of the clinical symptoms of breast cancer as contrasted with benign growths and calls attention t the valour symptoms and methods that are employed i arriving at an early diagnosis.

His conclusi as based on his review of the literature are as follows

The clinical signs and history must form the

basis for a diagnosis of malignancy i the breast.

2 Serology and other general laboratory tests,
as at present perfected, are not dependabled the diagnosis of these cases.

- 3 Repeated examinations at regular intervals, re desirabl to doubtful breast tumors, but the complet clinical picture should not be waited for before operation is d ised
- 4 The influence of physiological developme t and atrophy of the breast in which a tumor is present should be kept in mind

resent should be kept in mind
5. Most t mors. I the female breast at or near

the twentieth year are benign whereas t r nea th fortieth year they are malignant 6 Section through into the tissue of a tumor

- of the breast is never justifiable? It h purpose of diagnosa. Well-defined growths should include surrounding this who removed, but ill-defined ones re best removed with one-fourth or one-half the entire mammary gland.
- Cross-examination of the fresh specimen by well qualified pathologist—t the time of operation, is safer the examination of frozen sections alone
- 8 One abould not be conte t with a partial operation in breast tumors, if there is a question of malignancy. Only the removal i the lymphatics and the entire breast can effect a cure in such cases.

Learmonth M E Acute Mammary Carcinoma. Ca id M 1 J ig 6 490

It is estimated that acute mammars carkinoma occurs in about 1 per ent of all brea to armomata. Of the 40 ases reported only two are living past the he ever limit. The average age of enert is about 40 years. The nest thing noted to usualf a lump in the breast during pregnan. The our either disease 1 rapidly latal in fir mone to six mone his unless recognized early and appr prate urgs almeasures undertaken. The invitement spr adrapidly studies the measures undertaken. MacCarty W. C. and Mensing E. H. The Relation Between Chronic Mastitis and Carcinoma of the Breast $\stackrel{\wedge}{\sim} P = \stackrel{M}{M} J = i = i = 4$

From the stuly of 16 mammary car momata and 406 case of imple hrunic mastitudes emain questi na and their answer ha e been evolved (1) I car moma alwa a associated with chronic mastiti. In this series of ases the as scratt n wa Is bronic mastitus always as ociated constant with arrinoma. In the experience of the author. it certainl as n t 4 Are there any to s relative t the possibility of precan erous on ditions in chroni mastitis thi h point to a possible etiolomical relationship between carcinoma and chronic mastitis. There are three distinct onditions of cellular activity in this parenchyma of the mammary actions which bring chronic mastitis and mammary arcinoma into intimate a ociation and leg timately prohibit the c nsideration of the one without the consideration of the other. The microscopic pittures of the patholom of chronimastitus is given and the authors claim the line of demarcation between the acinus and the stroma is sometimes contused thereby making it impossible to accurately state whether one is dealing with arcinoma or not

There are three distinct histological pictures in chronic mastitis the hirt being characteristic of all chronic mastitis the recond, characteristic of some specimens of chronic mastitis the third in its earliest stages is associated with the hirt and second conditions. The third condition is a recognized jucture of carenomar The first is a beingin condition, and with our present knowledge the chinical significance of the second condition is still un

determined although it represent the precancerous histolom al pirture

From these ta the authors believe that there certainly is an assistation of chronic mactic is with ar inoma but annot a e-sci n in all that broin mastitt is an e-iol of all ta tor in mammary ar in orda.

The average age 1 the 6 gallent 1 h car inoas a q year in "purish with the a erage of 4 v art of 400 paint in imple hrom mattitis. A discharg from the mprie i presen in 4 per n i ll ar in ma a and 6 6 per cent of all hr ru ma iti. Trauma as a possible etcl mal tall rip the level pment of hrom mattil and ner is or atly minimized in the ene-ly the mpara is ly mall percentage or paint in bilt hi latti rectled in the histire. In a es of arif main the eries onl 6 gave a hi rv or trauma while 11 ith chroni mas i is gave imilar his ories. In this series i per ent i the patient with car inoma and per rewith imple he me mastitus were unmarri i whi h minimiles t a ertain degree th pe sibilit i lactation and it coincident in

Pathologi all arinoma is not a condition with his feperal fut upon the age of the uses but on some other condition of the tissues. Or all cases of chrominal in mastitus? ere diagnosed orrectly by the clinician the other 6 depended on fresh tissue diagnoses. In a cotthese anest or carcinoma of the breast chim all diagnoses of the glandular involvement howed that only 10 or 36 gs per ent actually had had it.

These errors emphasize the great alue of an immediate fresh tissue diagnosis in connection with operative interference. The authors belt we that practically one out of even in epitients with can er of the breast may be such from operation if the urgeon has a competent urgical pathologist a, sociated with him in his work.

From the foregoing facts the authors have emphasized the following ave points

1 Can er of the breast is always associated with chroni mastitis

2 The percentage of legitimate error in the clin rial hagnosis of simple chronic mastitus and carcinoma is respectivel. 6 per ent and 30 per ent 3 The percentage of legitimate error in the clin

1 al diagnosis of the condition of axillary glan is is 30 9 per cen

4. There are three distinct histological pictures

of chrome mastus the one extreme in its beings condition, and the other extreme in its beings condition. The mean with may be easily recognized is at present d ubtful.

The association of the two conditions is too.

The authors belie the f llowing to be the trul gical plan. Conditions in the breast which are associated with classical climical signs of arcanom. should be treated radically (a) In the doubtful cases of wooden near or over 3y years of age, the entire mammary gland should be removed for immediate examination. If primary or secondary hyperplasia be present nothing more abound be done if tertiary hyperplasia be present, a radical operation should be performed.

In doubtful patients, near or under thirty five years of age, a wide section of mammary gland, in cluding the pathological condition, should be removed for examination. If primary hyperplast be present nothing more should be done. If secondary hyperplasts be present the rest of the mammary gland should be removed and if tertiary hyper plasts be present the radical operation should be eccomplished.

Operation should be for the plant of the present the radical operation should be present the radical operation should be given by the present of

Lambrethsen, J. A Rare Mammary Tumor (Elm seltener Mammatumor). Need self 4 ch. Stock holm, 9 6, Europi 6

Lambrethsen describes and illustrates mammary tumor which be classifies as a schoecous carrinoms. The tumor aboved strips of clear cells lying in a grundwo k. Thysiline connective tissue. He bases the disgnosis on (1) the form of these cells which have the same developmental characteristics as a baseous grandular out They are of the law of the law of the cells which the proposition of the cells it which the protoplasmic granules gave at the first glance such a resemblance as to suggest the thought that the scheecous glands formed the starting point of the tumor. W. A. Bassessas

Paliance E. nd Roubler C. Primary Tumors of the Pleura (Les t meurs primitives de la plèvre) A d mbl 9 6 i 43

Primary tumors of th pleurs have Iways bee considered a raity the existence has even been denied by some. The uthors however conside the fact of their existence as indisput ble as evidenced by many undeniable cases in the literature They report three personal cases in detail. Th demonstration in each case was made at utopay Histologically in three cases were malignar tulpoms, a malignant tum rof the fibrous tissue, and a benign tumo of the fibrous tissue, and

Primary tumors f the pleurs may be divided into three categories benigo mixed, and malignant Benigo primary tumors are rare be tome observations of lipomata, chondromata, and fibromata have been recorded. In addition purely inflammatory reoplasms have been noted (syphilloms and tuberculomata) on the pleural surface. There is variety of fibrotuberculous pleural hypertrophy which can give rise to sessile and pediculated productions and may tetain a considerable volume.

In the class of mixed tumors the authors place the recorded cases of chondrosarcoma, myzofibromatom sarcomata, myzolipomatous t mors and the like. Malignant primary tumors of the pleurs, although comparatively rare are yet met with more frequently than the two preceding clauses. Pleural cancer presents listed in two forms, diffuse and circumscribed. Such tumors have been detained under a wariety of appellations, i.e., sarco-cardinomata endothelial sarcomata, proliferating lymphangitis, set, but all may be placed if the two clauses of sarcomata and endotheliomata. Sar comata of the pleurs are very similar to tum is of the same kind observed in other organs they may be fuso-globo- or giant-cried handotheliomata occur more f equently than sarcomata. They are ordinarily diffuse accompanied by abundant hem orthago tumefaction and nectastases are more often must with then in sarcomates.

Surgical Intervention is or should be confined to cases where the tun is a leastly decumented and of considerable volume as that it shows symptoms of compression. Guyot and Parceller in a go collected cases of maligna t t mors of the pleurs found 7 surgical cases i those in which there were no metastases. The apparent operability was 77 per cent. Three were operated upon, the others which would have been fut for operation having been found to the company in one of the operated cases the pa

tient was in perfect bealth two years later
Although est reation is rarely attempted, the
author thinks that prudent surgical intervent! will
be ble to metorat the prognosis where the tumor
ca not be urnically remo ed, particularly when
there is an early dugmosis W. A. Bripoux.

Goullipud and Arcelin Extraction of Free Bullet from th Left Fleura After Extablishment of an Artificial Percursotherax (Extraction d use balle mobile data players such a great fetallisment d un percursothera artificial) Lin mid 9 6

The case reported by the authors was that of a man who as found to have a movable bullet in the left pie ra. Belleving that extraction could be more realily complished by the prior establish ment of an artificial pneumothorar this was done to ording to the Forlalini procedure.

One month later when the patient was accustomed to breathing with one lung a wide incision of the picura was made, there being o appreciable respiratory trouble. The bullet being displaced a second incision was made in different intercental

space and the bullet removed.

The double intervention although it might have been avoided that the advantage of demonstrating how the patient had been accustomed by his prior pneumotors to breathe with only one lang. The a thous think that while the est blishment f artificial pneumotors is not indispensable in such cases, it is useful for the avoidance of the dangers of sudden-poeumotors avoidance of the dangers of sudden-poeumotors avoidance nor although of course such total pneumothors can be prevented in the course of operation.

Nevertheless in pieuropulmonary surgery artificial pneumothorax will find numerous indications, as in cases analogous to this. W. A. B. Excast Jaugens, F Two Cases of Mediastinal Tumor Treated by Radiotherapy (Deu cas de tumerus mediastinales traités par la radiothérapie) J de adiol 1 d'électrol 0 6 is 9

Radiotherapy is the only treatment applicable to intrathoracic tumors in which on account of their volume or their localization surgical intervention is either impossible or dangerous. The situation of such tumors in a region normally very permeable to the X-rays deprived of organs susceptible of being altered by repeated irradiations and allowing multiple ways of access give very favorable conditions from a technical viewpoint and permit the administration of therapeutic doses and the attainment of the limits of sensibility in the elements of the neoplasm.

The author reports the clinical data of two cases In one a woman of 6 irradiation was begun in January 1011 so that the anterior and posterior faces of the thorax were alternately exposed to weekly treatments. The dosage was 5 H penetra. bility 8 B filtered through a millimeter of alumi liter seventeen treatments the woman who had been previously in a very prostrate condition had recovered sufficiently to travel to Switzerland for recuperation. On her return she had seventeen more treatments and the author reports that all objective symptoms have disappeared. He points out that while the prognosus of her condition early in 1011 was fatal in December 1015 her very satis fa tory state is a very harpy result of radiotherapy

In the second case treated a child of 14 the results while not so satisfactory as in the first case still show a great amelioration. There is no notable dimunition in the size of the tumor but the activity of the neoplastic elements has been checked and there is a suppression of the toxic products due to it which has brought about considerable improvement in the general condution so that the child is rate of the companies. The size of the control health at the child is rate of the companies of the control health.

HEART AND VASCULAR SYSTEM

Ascoll and Masserial Projectile in the Right Lobe of the Heart After Tra ersing the Cara Inferiore (Proi title entro I orecchi tta destra del nore pers n t tra wroo la ca a inferiori) Cl & 0 6 x x 377

Preliminary radionerpy of the patient reported showed a piece of shraphel on the projection of the l ft iliac wing about the middle point. A second radioscopy made one month later showed the projectile in the cardiac circuit.

It was about to 8 mm in diameter inside the night lobe and it moved its position rhythrically with the movements of the lobe— Although the authors judging from published cases— hink that operative treatment appears to offer the only ultimate hope in such a case yet they healtated to operate in this case on account of the patient a condition.

II L BRENKAN

Bichat reports the case of a soldier wounded in the neighborhood of the right lung. Radioscopy showed a foreign body in the left part of the thorax at the external and lower limit of the shadow of the pericardium and heart which followed the movements of the heart and respiration. Later examina tions localized this body in the pericardium situated behind the sixth rib.

Operation performed two weeks litter under bloroom consisted in incision over the sixth rib re
section of the rib longitudinal linesion of the peri
cardium whi h was found empt). The projectile
was felt embedded in the lower extremity of the
right ventricle. The ventricle was caught between
two ingers and pulled forward incised and the piece
of shell removed by forceps some black blood es
caped but a few catgut sutures produced himmostasis. The pericardium was suutred.

There was no acceleration in the heart movem nts which remained at 80 until the end of the operation. The projectile weighed more than 3 gr and was 16 nm long. The condition appeared to progress satisfactorily for more than a week. On the thirteenth day after operation signs of pericardius appeared the cictura was opened and a quantity of scropurulent fluid drawn off but ten days later there was audden aphasia. Cheyne Stokes respiration was followed by death in a few hours.

At autops, the lung wound was shown to be uncicatized the trajectory contained a small fragment of bone with abundant supportation. Bighat be lieves that the pericardic infection originated in the intrapulmonary infection.

This is the fourth published case of extraction of a foreign body from the heart since the war began in only one of these cases was there a recovery. From a consideration of the general increature of the subject the author concludes that projectiles in the heart excluding the pericardium are not well toler ated that operatory intervention has given better results on the whole than non interference and that the subject opens up a new chapter in war surgery.

W. A. BELENAM.

PHARYNX AND @SOPHAGUS

Guttman J and Held T W: Carcinoma of the Esophagus Perforating into the Right Bron chus M d Rec 9 6 lxx lx 039

The author reports a case the interesting features of which are as follows

The onact of the disease appeared to be at the end of September 10.5 four months before the patient a death. The primary cause of the death, carcinoma of the exsphagus, had probably existed for a long time without giving prestically ny aymproms what ever There was no dysphagi no vomiting no fetor crove etc up to within a short period before

his death. A first ulous communication between the ersonhages and bronches had existed for some time. As a result of this, food particles passed from the former into the latter and in the course of time gave rise to bronchiectaria

The patient was sixty years of age and had suffered from digestive disturbances for ten years. The bronchiectasis gave rise to small pulmonary harmor

rhages and t cough thus obscuring the clinical picture by simulating tuberculosis.

The absence of pain and the comparative euphoria at a fever temperature of 10 and or is interesting The choking and coughing spells when the patient

attempted to drink is one of the most characteristic symptoms of exophagobro hial communication. LOWARD L. CORRELL.

SURGERY OF THE ABDOMEN

ABDOMINAL WALL AND PERITOREUM

Outland, J. H. and Clendening, L. Chylous Ascites and Chylothorax Due to Carcinoma of the Stomach. J Am M An o bry 1811.

A man, 46 years of age, felt well up to six months before examination April 16 9 5 The onset f his Illness was sudden. He had a sudden attack of dizziness and vomiting. He did not go to bed, but was weak and diggy and continued to feel much the same way for two months. He never vomited blood. For three months previous he had been troubled with indigestion, pain after meals belching and bloating. The bowels were constinuted.

March 27 915 the bdomen began to swell very suddenly and in a few days was enormously dis-tended. It was tapped April at and about a gallon of milky fluid was removed. April 8th it was tapped again and 15 gallons of ascitic fluid of the

same character removed. April 17th the abdomen was tapped and over a gallon of milky fluid withdrawn. The chest was ampirated at the same time, three and a half quarts of clear straw colored fluid being removed. fluid removed from the abdomen was milky in appearance, with a tinge of pink. It contained o per cent of alb min and fat and did not react to Pehling's solution. Microscopically it showed small fat globules and small specks in constant atomic motion. Leucocytes and erythrocytes were numer ous. The patient died May 3th

When the abdomen was opened at autopsy about three quarts of milky fluid escaped. The intestines were distended nd covered with a lymphatic exidate. The circum and appendix were enormously distended. Small lymphatic channels over the surface of the intestine were greatly distended. All the glands of the mesentery were enlarged. The entire meaentery was a thick mass of glands which were soft in consistency. The liver was enlarged and ordematous. The gall-bladder was large. There were no still stones. A tumor was prese t along the lesser curvature of the stomach, extending from the duodenum to well within the py lorus. The glands f th gastrobepatic mesentery were enlarged. No growth was found i the rectum. EDWARD L. CORPULL

Tuley H E., and Gra es. S. Chylothorax, Chylous Ascites, and Lymphosorcoms. J Am. If 411., 9 6 levi 844.

ged 58, married 36 years with two 4 woma children living had five brothers and sisters, of whom one died of brain fever one of typhoid fever and one of pneumonia those living being in good condition. The menopause occurred seven years previous without complications The patient had alw ya been robust the ormal weight being be t ree pounds. For several months sh. complained I pan n the scapular egions of both sides and could not lie a her back. For a year she had had pain and fullness in the enleastrium after cating

uthor first saw the patient October 4 1015. for an attack of dyapness, the cause of which seemed appeare that the chest we full of so rous and afbi lant rales and the breathing was typical of asthma.

November a careful examination was made of the thorax and the presence of fluid diagnosed in the left pleural cavity. A peculiar feat re of the chest findings t this tim was the presence of bro chial breathing o e the ent re left lung a terior and poswith i tense flatness over the left base. November as thoracentesis was done through the eighth interspace and three plots of thin, milky white fluid were w thoraw The ppearance was that of pus, but an vaminati n showed it to be free from cells and t be sterile chylous fluid. The relief from the dyspoora was almost unmediate there being very little cough following the aspirati n. From then until Ma ch the total quantity of chylous fluid re moved from this patient hest was 48 5 pints.

At autopay the head of the pancrens was involved in a t mor as described bel w The tall was neg

The lymph nodes from the eck of the pelvis, especially those lying in the posterior mediastinal and retroperitones! paces, were i volved in an apparently primary neoplasm which was growing around the structures in those regions, b t dld not infiltrate any except the bead of the puncreas. The cervical, anillary supraclavicular and infraclavicular and bronchial nodes varied in size the largest being bout cm in its greatest diameter were en capsulated and moderately firm and on sectipale flesh col and homogeneous except the last which were speckled with black. The posterior mediastinal nodes were much larger reaching a max imum diameter of 4 cm but were encapsulated and sefter and paler on section Below the level of the diaphragm the nodes seemed conglomerate in a mass larger than one s fist and involved the head of the pancreas. On section this tissue was mout pale homogeneous and typically like fish flesh while scattered in it could be seen lobules of nancreatic tissue. The lymph nodes along the lesser curt a ture of the stomach in the gastrohepatic omentum and retroperatoneal along the aorta were enlarged those in the gastrohepati omentum reaching a diam eter of 4 cm while those about the abdominal aorta decreased in size to the region of the bifur ation where they measured about 2 cm in diameter but were of the same appearance as those described above

In sits structures about the innominate veint were discreted primary incision being extended at right angles laterally along the left clavicle. No abnormality or rupture of the thorace duct could be found. In the posterior mediastunum duct the exophagus and vessels were surrounded by the tumor but none of these structures were invaded may roscopically. The heart lungs traches, exophagus sorts thorace duct painteress kidneys and suprarenals were removed on marsy. The duct was slit open and followed to its beginning branches. Its mucosa was smooth everywhere.

The microscopic diagnosis was lymphoblastoma

Chatillon F Spontaneous Pelvic Peritonization in Women La peritonisation spontanee du bessin de la femme) 1 d synée et d'obst 916 xill, 40

Several authors have from time to time shown that certain organs such as the epiploon colon etc. can among themselves form a protecting tent over the lover pelvis destined to prevent the spread of suppurative processes into the abduminal cavity

From a study based on Iwenty-seven observations made by Beuttner in the Gynecological Clinic of the Unitersity of Geneva in which he studied the zact condition in which the abdomen was found on making a laparotomy he sketched certain conclusions which he recently published Chatillon now publishes the study on the same lines based on a much larger number of cases viz 100

Sometimes at a laparotomy the inflamed genital organs are found to be so well protected by their neighbors that they are scarcely seen the inflam matory process has been spontaneously pertonured and the diseased parts isolated from the abdominal cavity hindering propagition of the infection. The object of the author's research is therefore to the fitner are any rules according to with the different organs act toward each other or bow one or several diseased organs are projected by their neighbors.

The author considers this spontaneous peritonization by means of the rectum gmoud excum small intestine epiploon etc. He in its that spontaneous perit nization has been produced in 100 cases as follows:

21 times by 1 organ 30 times by 2 organs 26 times by 3 organs 11 times by 4 organ 5 times by 6 organs 5 times by 6 organs

While Bliesener found that the grand epiploon as most often util teed the author's research howed that the small in testine and sigmoid were the most frequent. He draws these general conclusions from his study.

draws these general conclusions from his study.

If the annexes descend into Douglas's pouch along the posterior wall of the uterus and are peritonized by adhesions which the rectum, uterus bladder etc form around them. In this case the peritonization will be effected by the organs of the lower pelvis. It will be two peritonization.

If the annexes for any reason do not descend into Douglas a pouch and consequently remain in good position peritomization will be effected by the organs situated above them or in their immediate vicanty; e c the emploon coccum sigmoid boop or small intestine. This process the author designates as high peritomization

3 The combination of these two methods will form a third categor, which comprises complicated cases where peritonization proceeds at the same time on the part of all the organs. This may be termed mixed peritonization.

Hence the general rules for spontaneous peritoquation of the pelvis in woman are (1) by means of the lower pelvic organs (2) by means of the organs of the intestinal tract (3) simultaneously by the lower pelvic organs and those of the intestinal tract W. A. BENCHAN

Bench W M Some Observations on Hernia in Relation to Intestinal Stasis. T im Proceed Soc Det out 9 o June

After reviewing the theories of Keith relative to nodal zones situated at different levels in the intestinal musculature the author makes the following observations.

I We have tried to d in intestinal stass as a physilogi o-anatom disturbance of peri talsis by an inhibiting affuen e through the nodal zo cs of

the myenterium located in the assophagogustric junction, the duodenojejunal area, the lleocecul region, and the rection. This demonstrated in the laboratory must be verified clinically

 Anatomic distortions, as kinks, adhenous, ptoses, etc. lead to stasis by disturbing the ganglia controlling peristalsis.

3 Hernia is a frequent manifestation of visceral displacement concomitant with stass.

4. Long truss wearing with great pressure tends to prod ce rectal disease

GASTRO-INTESTINAL TRACT

Terry W I and Kilgore, A. R. Congenital Stenosis of the Duodenum in a Adult J Am II Am a 6 lvd. 214.

A man aged 24, presented executally egatic family and past history and habits. Hu illness begun at the age of 2 with year of intermittent rether indefinite pain in the lower side me followed by the cande half years of freedom and then four years more of similar tracks at intervals if from three to for weeks. The pain was always become the unabilities, extending 5 cm to either side if the middlice without radiation. There was no definite relation to food. It was relieved by hot drinks and occasionally by defect too. It was mustly worse at hight

He had had o definite pain for fi years b t four years ago vomiting had begun nd had grown progressively worse, usually coming after the evening mest, sometimes aft other mests. Ther had never been hemateman o medical.

The abdomen was acaphoid except for prominence about the mbilious (diste ded atomach) over which there was ma ked peristaliss from left to right. The lower border of th. stomach was seen and percussed midway between the umbilious and

the symphysis. At operation the stomach was found to be mich dilated and I win the bdomen. There were som old dheal as across both the anterior and the posteri r aspects of the tomach toward the pylon. end but none abo t the d odenum except two ery thi strands between the pylorus and gall bladder The pyloric ring was much dilated The first por tion of the duodenum was dilated the upper wall forming a d finite pouch. Just distal to this dilated portion at about the junction of the first and second portions of the duodenum and above the entrance of the common duct the intestine was evenly constricted to one-third or less of its diameter for abo t s.cm. There was no thicken ing of the wall and no scars could be found abnormalities of the peritoneum to account for the constriction.

A posterior gestro-enterostomy was done and whe the st much was cut into marked thickening of the wall was noted in spite of the dilatation of the organ, indicating long-standing obstruction.

The patient vomited during the first forty-eight

boun following the operatio the vomitus routain ing considerable blood Following this h was delitious much of the tim and on this coount was given occasional mand feedings. On the fifth day he was apparently much improved and took coo siderable noomahnent but vomited small amounts twice during the afternoon. Quite suddenly in the evening the pulse rate increased and respirations becam shall w and rapid and be gradually sank into come and died! six hours.

At necropay there was found t be ma ked dilata ton if the atomach with partial breaking down of the gustro-enterostomy wound leakage of stormach the peritoceal cavity on beginning peritonitis. The constriction of the dodenam presented the appearance of an obstructing fold of the dodenam wall rather than of a narrow tube 5 mm long as it had appearance for fination. Growiny and microscopically the ocatri tion was covered with ormal mucous membrane and careful esserts failed t reveal any scar tissue or other voidiness. Fold suffers in a Danay In L. COMMIL.

Cooks, J. V. Rodenbaugh, F. H. and Whipple G. H. Intestinal Obstruction 1 a. Study of Non-coagulabl Mitrogen f th Blood J. Exp. M. d. 0, 6 cm., 7

This communication deals with analyses of the blood in Interstand obstruction. Interstand closed loops, and other cute intovacations. The tables of a figures for on-congulable nitrogen ures nitrogen and a some instants the total nitrogen particle in the blood. The thors interest in this st dy fith blood was aroused by a communication of Tileston and Comfort who in a large series of human cases reported three cases of testinal burneries with the communication of the properties of the communication and the communication with other x retringuist works.

They found that most cases of intestinal obstruction especially with igns of acut intorication bowed high on-coagulably blood nitrogen and t seemed; them that this factor might be of alue if diagnosis and especially prognosis of acut abdiminal coolitions. They believe that this noncoagulable trogen determinat n is of value in v from cute! to receation. If the readily is high,

may ass me a da gerous grade f int axention, but on the contrary in may not assume that a low reading gives evidence I slight introduction because f its outcome may be associated with a low reading. It is f considerable value to know that the non-congulable nitrogen of the blood may show high readings in other conditions besides renal discussions.

On the other hand, determinations of the blood ures alone are of somewhat less value in tudying the retention prod cts in the blood in these conditions. In their experimental animals the blood urea has varied from less than 30 per cent to more than 80 per cent if the total non-congulable nitrogen, and, while a high urea reading is the rule the variations in the urea curve and the curves of the other non congulable autrogenous substances are so great that the urea reading is a somewhat unreliable under of the extent to which non-congulable introgenous substances have accumulated. The authors work seems to establish the following facts:

Intestinal obstruction as a rule is associated with an increasing amount of non-coagulable nitrogen in the blood. With acute interaction the use in non-coagulable nitrogen may be rapid and reach as high as three or even ten times the normal amount. With more chron, interication there may be little or no use in the blood non-coagulable nitrogen. Closed intentinal loops show exactly the same picture and when combined with obstruction may save yer, but nitrogen tendings.

2. Acute proteose into vication due to injection of a pure proteose will show a prompt rise in blood non coagulable introgen even an increase of 100 per cent within three or four hours. These intoxications also show a high blood conveyt of creatinin and urea. The residual or undetermined introg n may be

very high

3 A human case of intestinal obstruction with surpry presents blood findings exactly similar to those observed in many animal experiments. Clinically the non-congulable nitrogen of the blood may give information of value in intestinal obstruction. A high reading means a grave intostration but a low reading may be observed in some futal cases and gives no assurance that a latal intostruction may not supervise. The kidneys in practically all these experiments are normal in all tespects.

It is possible that protein or tissue destruction retrieve than impaired climinative function is responsible for the rise in non-congulably hitrogen of the blood in these acute intorications. Translations of destrose solutions often benefit intestinal obstructions and may depress the level of the non-congulable nitrogen in the blood. Some assession no change in non-congulable nitrogen following translations and discusses, and as a rule such cases present the most sever insortation.

GEORGE E BETON

Power D : A Clinical Lecture on Volvulus Am. J = S = 6 - 910 exc. 78

Power defines volvulus and states that the exact mechanism of its production is unknown but that two necessary factors are (1) congenital or acquired defect in the intestinal strackment allowing free mobility and (2) a condution producing an artificial pedicle. He cities are crosses from which he concludes that volvulus so no of the causes of acute intestinal obstruction and that it may appear an newborn children although thus is rare. He be lieves that volvulus requires for its production a loop of bowle lying leas securely packed than usual in the abdominal cavity a leaded bowel and irregular persistants. Frequently there is a tailet of one one and a half or two turns in the loop upon itself usually the mecentery, a long in these cases.

The onset of volvulus is sudden and painful and occurs in persons who have had no reason to be here they were not in their ordinary health it may occur without any known cause or it may follow an injury to the abdomen generally the pain is persistent or is characterized by exacerbation The position of the volvulus determines the time of the appearant e of the signs of intestinal obstruction When the armoid is involved the signs appear early when the execum is twisted there may be a delay till the larger intestine by empti ditself or it may be muck d by a discharge of flatu generated in the great bonel. The inset of comiting may be delive for it some cases may be entirely absent but usually it is a marked feature of the condition hrat the temperature and pulse are not altered

Abdominal distinction is limited early to the portion of by nel involved. In its incipiency there is no rigidity of the abdominal wall, local tenderness over he actual gest of the volvinus is present but is not year, marked until the onset of contonius.

Strangulated herma acute perforation of the stomach or duod num bulary and renal colo acute intestinal obstru iton due to strangulation by a band hamorrhagi pan reatitus thrombosis and embosism of the mesenteric vesici and appendicitismust each and all be consid red in the diagnostic

The prognosis at the present time is extremely unfavorable the improvement in this tegard depends entirely upon the early recognition and early operation. In looking up the records in his hospital from 1850 to 1915 the author hads that there were 25 cases of volvulus 14 men and 11 women. Twen two-ne of these nations did!

In the after treatment of volvulus the author believes that nothing should be given by mouth for the hirst twelve hours after the operation though the mouth may be mased out with warm waiter from time to time if thirst is districtions. Three or four does of primitary extract may be given hourly by injecting 0 5 to 1 cens into the muscles, but he hope of causing contraction of the involuntary muscles of the body, thereby simulating the un a nated muscles of the latestine. The rectal tube should be passed every four hours if the distention is very great

In general the after treatment is directed forward the reduction in the tympanites as he recognizes that the tympanites is a measure of intestinal pare as and that as this is reduced the patient will improve East C ROBITIES.

Abbout A W. The Early Diagnosis of Intussusception in Children Under Three Years of Age J La 41 9 0 xyry 10

The author gives a sense of statistical observations made upon twelve cases of intustive prior in lifents under three years of age. The diagnosis was made before operation in all but two and the linus-size perior was found to be teocaci in all cases.

In oo per cent of the cases the it ck began by a sudden violent abdomin I pain accompanied by re

gurgitation of stomach contents the child being otherwise well. This pain is recurrent varies in intensity but is regular in periodicity. With the pain the child assumes pecular positions, generally proce. In 5 per cent of the cases, collapse quickly occurred and the pains were then merely indicated by means and drawing up of the limbs.

In 02 per cent an abdominal tumor could be made

out in the course of the colon.

In 6 per cent there were o faces in the stools. In 8 per cent of these mucus was the chief constituent of the stools. In 77 per ent f the cases, blood was present i the stools only after the second

In nearly all cases the abdome was not distended,

flaceld, and scanhold.

In exceptional cases vomiting was absent and in 81 per cent of the series it only occurred after the second day

Positive identification of the intresusception by rectal examination is pathognomia and was demon-

strated in only 55 per cent of the cases.

The virulence of the disease and its mortality depend not so much upon the time elapsing before operation as upon the intensity of the strangulation of the mesenteric circulation. How ver the earliest possible diagnosis and immediate operation is imperative.

In the series, 8 recovered and 4 died. In those in which collapse quickly followed th onset all died. While in those in which collapse was bent 8 e-covered and on died P M Char.

Sweet, J. E., Peet. M. M., and Hendrix, B. M.
High Intestinal Studie. Ann Surg. Phila. 9.0
lxili, 720

The authors carried out a series of apenum its to determine the cause of death in high intentional observation, the claused picture [which suggests gray constitutional dustwithcase of tori anture. Draper idea that the torin is a normal prod or [the duodenium which under normal conditions is neutralized or der tified by the jins m is supported. The authors began with the admitted clinical fact that the symptoms of our pancrealities and our high obstruct I are so much allie, if not ideatical that a differential diagnosis can be made only at operait a nat (bits suggested that the 1 that agent might in some way be connected with the pancreatic since.

creatic junce.

It is believed that high i testinal betruction is du to the highly tonic properties that have been found in the proteone tage of protein digest on. The normal ferments of the stomach superior of the normal ferments of the stomach superior of the normal ferments of the stomach superior of the normal ferments of the stomach superior of the protein of the foot to the peptoes stage, from which the digestion is carried to the amino-acid stage by the ferments of the pancress and the intestine. The intestinal place is not supposed to contain any protolytic ferment except the ferment ereptin which can digest the proteins of the protein supposed to which can digest the proteins of the protein supposed to contain any protolytic ferment.

ten casein, but no others, while its chief function is to digest the proteoses to the amino-acids. But either gastric or pancreatic ferment is capable of producing a totic proteose. In addition, many bac teria can digest the protein building-stones to the hughly totic amine compounds. Further the substance lecitish can, by the action of the fat splitting ferment lipase be broken down with the formation of the choline bases, som of which such as choline and neurine, are burtly total.

Whipple has demonstrated that the toxic body found in their high loops is a proteose and that this purified proteose a ould exactly reproduce the symptoms of high obstruction when injected i to nor mal animal.

Two outstanding features of the authors experi mental work re () the added demonstratio of the fact that a gastro-enterostomy opening does not function in the presence of a normal pylorus (2) the explanation of the similarity between acute pancreatitis and cute high batructi n they alike because they are both essentially the same thing an into deatton with the toxic products of protein cleavage, in pancreatitis certainly due t the proteolytic ferment of the pancreas in high obstruction not necessarily perhaps, but in their opin ion in all probability the same toxin, produced by the same ferment. In pancreatitis the escape of the products of the direction of the pancress into the tissue permits the intoxication in obstruction the conditions of batruction permit the absorption f toxic products, which under normal conditions would either not be formed, or if formed, would be immediately broken down to non-toxic products.

The utbors refer t the failure to find any definite poison not no difform of statis of the large in testine and draw attention to the fact that in position across the transverse d odenum, prod ding as has been reported a dilated duodenum. Removal of the colon would relieve this dray and the from predicate the idea and the thorn predicate the idea that twould be well to consider the chronic borpti of nuclear position.

C. G. HEYD

Fowler R. H. Complete Congenital Atresia f th Heum. Med Rec. 9 6 lvvvi 30.

th reports the case of a baby whose deli ery was normal and casy no f reeps being used the weight at birth being about seven pounds. I miting commenced about fifteen minutes after birth. The vomitus was green, flaky and thick The vomiting contin ed at without special odor intervals d ring the night and the following day The abdomen was slightly distended and tense There was no visible peristalsis and no masses were seen or felt. There were no external congenital anomalies. The rectum easily admitted the little finger no blood escaped or appeared o the gloved finger No masses or betruction were felt. The genitalia were normal.

At operation a right rectus incision was made.

A large amount of thin serous fluid escaped on open ing the peritoneum. The small intestine pre-sented It was of dark color and distended six times the diameter of the neighboring loops. This distended loop of gut literally popped into the wound. It was blind and free without fibrous cord connection The mesentery down to its root was also lacking at this point The gut above this point was less dilated than the blind pouch The bladder was full and the stomach distended. No stenosis or change in the pylorus was noted. The duodenum was dilated slightly more than the commencing iejunum. In a hurried search the lower end of the lleum was not found. The appendix was normal. There was no persistence of the embryonal type of cacum. The latter was firmly attached to the posterior abdominal wall. The intestines were moderately congested. The upper free end of the small intestine was sutured to the abdominal wall and the abdominal wall closed in layers about the protruding gut Enterostomy was then performed by the thermocautery The patient died five days later

At autopsy it was found that the total length of the small intestine was 56 inches. The ileum ended in a small blind pouch 22 5 inches from the ileocecal valve one half inch in diameter. The wall of this was thickened and bulbous for a distance of three-eighths of an inch. It was slightly curled upon itself The segment distal to this cul-de sac was patent. There was a defect in the mesentery at a point opposite the atresia of the ileum. The upper blind pouch ended at a point 33 5 inches from the pylorus. It was very much dilated for a distance of six inches. The widest diameter of this portion was 1 75 inches. The duodenum had no mesentery the cocum was located in the right fliac fossa there fore rotation of the intestine had occurred. The ileocecul valve and the pyloric sphincter showed no change. The liver gall bladder and ducts and stomach were apparently normal. There was an accessory spleen. EDWARD L. CORNELL.

Huggina, R. R: Absence of Muscular Tone an Important Ethological Factor in Post-operative Ileus. Tr 4m Ass Obst & Grace Indianapolis 19 6 Sept.

Distention and stass, to a varying degree follow most laparotomies. This is usually considered a temporary paralysis a reflex action through the please of Auerbach and Meissner as a result of manipulation and trauma to the visceral peritoneum. Aside from the paralysis accompanying peritonitis there are occasional cases where infection can be excluded in which the patients die from paralytic illeus. This may occur when least expected and where there has been very little intra abdominal exposure and manipulation. The comparative frequency with which it has occurred with vaginal hysterectomy is significant because there is very little exposure and handling of intestines in this procedure. Careful pre-operative operative and

post-operative treatment is important in lessening post-operative paresis, but occasionally in spite of this an aggravated form of the above condition occurs and death ensues after exhaustion of all known methods of relief When there is evidence of chronic fatigue with poor muscle tone after chronic in fection or long continued strain there is always greater difficulty in dealing with this post-operative distention. The author believes that in certain instances where death occurs from so-called paralytic ileus, it is primarily due to lack of muscular strength in the walls of the stomach and intestines As a result of observation of various degrees of distention in routine abdominal surgery we find that this depends largely on the general muscular tone in the individual previous to operation and the amount of exhaustion incident to the operative procedure and the effects of the augsthetic.

Keith has recently called attention to the presence of nodal tissue in the bowel similar to that in the heart. This is located at various points in the intestinal tract and acts as pacemaker for that particular portion. It is neuromuscular in character and suggests the intimate relation that exists be tween the muscular and nervous system, and the disturbances that may arise if either is below the normal in efficiency. A block may occur as in the heart at any point where one rhythmical zone passes into another Bayliss and Starling demonstrated the intrinsic beat in intestinal muscle. Magmus demonstrated that the strips beat more actively when removed from a normally fed animal than from one that was not digesting. The intestinal tract has an intrinsic tone regulated by extrinsic nerves. Tonic contraction and rhythmical peristal sis disappear when there is general bodily weak ness, and when the depleted central nervous system fails to deliver the necessary tonic impulses. Post operative distention varies in direct proportion to the strength and tone of the general muscular system Patients with poor general muscular tone require more careful preparation and greater efforts to minimize exhaustion from ansesthetic and opera tive effects.

Moschcowitz, E: The Pathological Diagnosis of Diseases of the Appendix. Ann Sug Phility 16 brill 697

Moschowits believes that in 90 per cent of cases the diagnosis of a present or previous appendicitis may be easily recognized by the naked eye. He holds that the conventional method of longitudinally sitting the organ to see if the appendix is diseased and to what extent is wrong. In acute appendiction the longitudinal method is not so apt to lead to mistakes. The author advises simple transverse incisions made at various levels. By such incisions it is possible to tell accurately the quantity and topography of the crudate the width and conforms then of the lumen and the evidence of a lumen the relation of the mucosa to the muscularis. Emphasis is a placed upon the observation that a local peri-

toulth is always present in the early stages of discase, and that the absence, even growly of a localized appendicular peritoultis practically excludes an acute appendicular peritoultis practically excludes an acute appendicular. Acute perforation are, i the opinion of the suther due to the direct destructive action of the bacteria upon the wall of the ppendi associated with extensive tension upon the crudate within the lumen. Thrombosis of the meanterior lumplays a small part in the etiology of perforations.

The path lorical anatomy of crite appendicitis is summarized as follows (1) The infection is always enterogenic as evidenced by the invariable origin of the lesion from the mucosa. () The lesion of acute appendicitis is not a catarrhal inflammation as understood in the pathological sense (t) The infection starts in the crypts of the mucous membrane. Additional weight is lent to this contention by the fact that approximately nine-tenths of the lesions of acut appendicitis occur t th tip of the appendix where stagnation is most apt to occur This fact makes untenable the contention that appendicitis is occasi untily due to a carcitus or lesions of the so-called Gerlach's valve by interfering with the drainage of the organ (4) The nathological lemon fairly corresponds to the duration of the Illness. (5) The essential pathological lesson of acute appendicitis is a membranous inflav mation,

a so-called diphtheritic inflammation. In healing appendicitis the course of events is as follows. The expedite or membra breaks down. becomes necrotic, and leaves an ulcer which gives birth to granulation tissue. The extent of this granulation tissue depends upon the extent f the destruction of the mucosa. If the mucosa has bee completely destroyed, no regeneration of epithell m is possible and the ensuing organization of the tissue results in complete obliteration. If the mucosa has not been completely destroyed, the epithelial lumen is restored, a tricture is formed the size of which is obviously in inverse ratio to the extent of the mucosal destruction. At the same time the formation of new connective tissue in the muscular enate leads to the changes deformity and separa tion of the fibers by newly formed connective tissue. In the peritoneal coat the formation of the new con nective timue and destruction of the surface epathe-Hum also lead t two changes thickening and forma tion of adhesi ns. The histological characteristics of a bealed o chronic ppendicitus ar therefore the following () a narrow lumen (stricture) (2) com plete obliteration of the lumen by new connective therue (3) the beence of mucosal crypts. (This absence indicates except in cases where the lumen f the appendix has been dilated from other causes. that a precious scute suppurative inflammation has taken place This phenomenon is important in differential diagnosis in cases where there is question as to whether the lumen of the appendix is narrower than normal.) (4) the widening of the s binucous connective-thrue sone (5) the attenua tion and diminution (or even complete duappear ance) of the lymphoid timue (6) the infiltration of

the muscula coats by new connective tissue and consequent deformity (7) the thickenlig, increased density and deformity of the peritoneal coat.

As a result of the a 'hor's bservations it is tated that an acute presidents always gives rise to per manent pathological changes and secondly that a normal presidence and the second of an cute attack. Of the diagnost c haracters [healed or chronic predicting great emphasis is listly upon () strictur () old teration. () disappearance of optic (4) wideling of binurous. The appearance of petechal pois scattered throughout the mucous is considered to be due to operative training. Divertical modifies the product of the product o

In regard t carcinoma of the ppendix the a thor calls ttention t cert in currous features of the disease C remoma f th appendix differs from carci oma of other o gams and especially of th intest nal tract in number of feat res () It occurs as a rul in m h younger individuals, most commonly I the second and third decades. Two of the uthor a cases exemplify this. () Carcinomat of the appendix, both pathologically and clinically re of very low grad of malignancy pendix ca cinomat esembl other carcinomat only in thei lyeolar tructu and the epithelial type of cell. In other respect they differ hist logically from other carcinomat The cells a e maller and less atypical the nuclei show little ranation in size and shape are less rich in chromati and compara tively free from mitotic tigures. I nally there is less tendency t vasion of eighboring organic structures nel practically no t adency to metast Indeed the author finds these pathological data brought out by clinical experience. Carcinoma of the ppends has by far the best prognosis y cancer in th human frame. The author believes the reports of fital cases re rare. Per haps one of the reasons for the f vorable prognosis is the early diagnosis f ppendicula pain, du to th prompt interference with the drainage of th narrow lumen of the organ by the growth of the tumor (3) The vast majority of carcinomata [the appendix are of the solid type whereas carcino-

mata of the intestine are of the glandular type.

After a consideration of the a bject as a whole the author arrives t the following conclusions

1 The pathological lesion of acute ppendicitis represents a supparative process from the very beginning. The earliest leason is as pathogenomous as the primary leaton of yahilis and all the subsequent stages if the disease within the organ are disretly traceable to the prend and development of this lesion. There is no pathological evid nos that an acute cuterrhal inflammation of the appendix occurs.

The changes associated under the name.

chronic appe dicitis (stricture, obliteration, etc.) are pathogenetically the healed products (the acute lesion. According to this interpretation, chronic appendicitis is not a continuous progressive

inflammation, but an end product. There is no pathological evidence of "involution of the appendix, or of chronic catarrhal inflammation of

the appendix.

The only justifiable classification of inflamma tion of the appendix, therefore is the following (1) Acute appendicitis (2) Healing of subacute appendicitis. (3) Healed or chronic appendicitis. (4) An acute localized peritonitis with the forms tion of fibrin and limited to the site of the lesion is always present in acute appendicitis as early as twelve hours after the onset (and perhaps earlier) so that the absence grossly of a localized peritonitis in suspected cases, is eo spso evidence of absence of acute appendicitis (5) In addition to obliteration and stricture, attention is called to two new easily recognizable, constant, and pathognomonic signs of chronic appendicitis namely (a) absence of mucosal crypts (b) marked widening of the submucous connective tissue zone. The latter sign is especially easy to determine upon cross-section of the organ, and is recommended as the simplest way to determine the presence or absence of a chronic appendicatis. (6) Cross-section of the appendix at various levels is far preferable to longi tudinal section to determine pathological changes

Valdez, G: Morphine as an Early Diagnostic Element in Certain Forms of Acute Appendicitis (La morfaa como elemento de diagnostico precos en ciertas formas de apendicitas guda) Press and Argent. 19 6 il. 430.

Valdex uses morphine in the diagnosis of various as appendicular nature believing that this method may be applied in those cases in which the diagnosis is doubtful. In effect by making an injection of morphine in such cases the reflex defensive phenomena diappear (contracture of the abdominal muscles) which allows a much better abdominal examination, as at the end of an hour after the injection the pain can be localized with free tracticess.

Valdez thinks that morphine can be usefully em ployed in some cases of difficult diagnosis.

W A. BECKEAN

Robinson, J E. The Leucocyte Count of Appen dicitie. h 1 If J 19 6 cm 175

A report is given of 200 appendices removed at operation at the King's Daughters Hospital Temple Texas, in the last two years in which sections were made of the appendices and records made of the blood-counts made before operation being considered.

Reports are also given of the blood-counts in 200 cases in which records were kept of the blood counts but no sections made of the appendix.

Fifty two cases, or 21 per cent were diagnosed as active inflammator; by both the surgeon and the pathologist the average leucocyte count being 18 000 and the polymorphonuclears 818 per cent

Sixty five cases, or 32 5 per cent were diagnosed as chronic by both the surgeon and the pathologist the average leucocyte count being 10 161 and the

polymorphonuclears 76 per cent.

In 40 cases, or 20 per cent the appendices were removed while operations were being performed for non inflammator, conditions in the abdomen. In these cases which both the surgeon and the pathol ogist reported normal the average leucocyte count was 8400 and polymorphonuclears 67 5 per cent

It will be seen that the surgeon's report made with the history and appendix before him corresponded with the laboratory report 157 times or in

78 s per cent of the cases.

Fourteen cases were diagnosed as active appen dicitis by the surgeon and as normal by the pathol ogust and in these cases the average leucocyte count was 11 000 and polymorphonuclears 72 1 per cent.

Twenty-four cases diagnosed as chronic appendicates by the surgeon and as normal by the pathologist gave an average leucocyte count of 8 000 and a polymorphonuclear of 65 8 per cent.

In 5 cases reported as active appendicitis by the surgeon and as chronic by the pathologist the average leucocyte count was 7,450 and the poly

morphonuclears 62 5 per cent

Presuming that the findings are correct and that the work is that of surgeons of everage ability it will be seen that the surgeon is incorrect in his conception of the pathology of the appendix in 21 5 per cent of the cases. I we've per cent of the normal appendices were diagnosed as chromically inflamed Seven per cent of chronic cases were diagnosed as active and 25 per cent of normal appendices were diagnosed as active and a 5 per cent of normal appendix swere deeming feature of the surgeon's report in no in stance was an inflamed appendix diagnosed as normal and his efficiency along this line is easily 100 per cent

In the second series of 200 cases in which sections were not made 93 were disgnosed as actively in flamed and 55 showed pus either in or around the appendix these gave an average leucocyte count of 20 000 and a polymorphonuclear of \$4.6 per cent. The highest leucocyte count was 98,000 with 89 per cent polymorphonuclears. The lowest count was 10,000 leucocyte with 86 per cent polymorphonuclears.

Thirty-eight cases diagnosed as active appendicitis showing no pus gave an average leucocyte count of 18,000 polymorphonuclears 83 a per cent.

Six cases in this series gave a leucocyte count as low as 12,000 with an average of 83 per cent poly morphonuclears. In 107 cases diagnosed as chronic appendictis the average leucocyte count was 10,000, polymorphonuclears 70 2 per cent

It will be noticed here that the cases showing pus gave a leutocyte count of 11 000 and a polymor phonuclear count of 18 per cent higher than those in the series which were sectioned and pronounced to be actively inflamed, while the cases showing no pus gave practically the same count as the series sectioned, namely 18 000 in the sectioned series and 18 500 in the series not sectioned with a difference of only 0.4 per cent in the polymorphonuclears.

EDWARD L CORNELL

Leigh 5. Treatment of Suppurative Appendicitie. South If J=g 5 i 5 3

As soon as appendicitle is suspected, the head of the patient should be immediately elevated and the patient kept on the right side. In such position if rupture takes place, the septic fluids will either remain at the sit of the appendix and become walled off or gravitate into the pelviv where they may be more salely taken care of by the serous membrane, be more conveniently reached t the time of oper ation, and the dangerous region of the upper abdomen will be thus safeguarded

The quertion of transportation is most important, the patient's shoulders being well p opped up and inclined to the right side. This must be strictly done in all carriages, wagons, trains and ambulances used for the sick. The last named should

always be equipped with an elevating stretcher. When a case of suspected suppurat ve appendictle reaches the bospital, he should be immediately placed on an elevated bed, on the right side with an ice bog applied. Except in desperate cases, a low turpentine enema should be give

The anesthetic is of majo importance. The author has used nirrous orde-oxygen in one cases, not only without mortality but without any bad effects, either direct to indirect. It is especially hedpind in severe approducitis, dding practically nothing to the shock, producing no ritiation of the lungs or kidneys, and accompanied either by no

nature or a minimum arrow t
The location of the incision in cases f suspected
suppurative appendicitis in important Drainings
through the old longit diffial incision leaves a very
weak apor which nea by always requires operation
to close. For several years the author has emply yet
the transverse incision. The abscess is opened
after walling of The pois idramed and the appear
this cought in most cases. The extra by is depend in

and gaure rubber tube drains meered.

In suppurative appendictles, in which the abscess
has not been walled off by adhesions, and in consequence of the general peritonent cavity has become infected, the transverse incusion must be
stretched to allow free access to the peritoneal cavity.

Incisions are preceded by meeting nowocales
solt then to produce norwe-blocking. The great
possible gentleness is exercised in the handling

of the tissues.

A irrigation should be used, but the pus should be hiped out carefully with sponges. After all the us which is coesible is than eleaned out paid are cautiously inserted and the appendix searched for and removed and the paid being regular selfent for and removed and the paid being regular selfent. The pelvits is often found full of pus, which should be removed by surface.

Everyan L. COMMILL.

Shaw H. A. Th Treatment of th Retrocaecal Appendix. Ass Surg Phila 9 6 kini 7 5

The author refers to the simple clean, bloodless technique for the removal of retroexed appendix by mobilization of the excura and colon. In the etdology of a retroexed appendix the following factors are emphasized () the influence of pertonced ad heasons established during the descent of the excura from its subhepatic position to the lifts closes () the inherent curve of the feetal pouch (3) the uncound development of the pouch.

The whole suggests the diagnostic points necessary to determine the position of abstrant appen diese careful survey of the encum (with the embry ology thereof in mind) noting the relative size and position of the terminal sacculi its topographical personal relations careful palpation. The technique emphasizes the mobilization of the occum and portion of the colon necessary for exposure, and after exposure separation of adhesions and delivery coccum is quiesed and the incidion like in the parrelat personnel does do youtures. The stump of the appendix is tracted after the accepted manner

C G Hern

Frazier C. II and Poet M M Experimental Colonic Stasia. Ass. Surg Phila. 9 6 Ivill,

The authors believed that a maximum amount of stasis without partial obstruction could be secured by a simple reversal if the large intestine and carried out their experiment by the reversal of the colon for a length of four to six inches above the sigm id. Two sets of experiments were carried out, as follows:

With reversals of the colon jer as the stools were soft and well formed and all the does gained weight. The following substances were demonstrated by qualitative tests in the urine methylamin trimethylamine tetramethiendiamine, pentamethylamine pentamethylamine pentamethylamine pentamethylamine pentamethylamine pentamethylamine pentamethylamine pentamethylamine pentamethylamine were not demonstratible. The urine of these dogs as well as the batances obtained after chemical isolation of the mixed bases was injected intravenously but no no-ticeable toxicity could be established no did the curve of blood pressure differ from that to be noted

fellowing the injection of normal canine urine.
The results of reversal of the colon in dogs with
Eck fixtula Ahcayyalk ligature was tied around
the portal win close t it as entrance into the liver
thus forcing all of the portal circulation into the
versa cava. In these experiments the stools were
therefore the colonial colonial colonial colonial
The chemical examination of the urin was the same
as before, both qualitatively and quantitatively,
showing that the liver had not removed or changed
the substance absorbed from the colon.

The authors conclusions were that mere stagns tion of frees in the colon of the dog, when n a nor mal mixed diet does not lead to the formation of toxic substances of note, at least in the presence of the normal flora of the canine colon.

The fact that these dogs remained in perfect health and gained in weight indicates that simple colonic stasis in the dog is harmless and certainly suggests that the dire effects attributed to colonic stasis in man are in part at least due to some other cause than the absorption of the products usually formed in simple facal stagnation. C G HEYD

McArdle J S : Alternatives to the Operation of Colotomy Pract | ner Lond. 1016 zevi, 578.

The after-effects of so unsurgical an operation as colotomy are very distressing to the patient author believes that every effort should be made to substitute some more finished procedure for this crude method and suggests that either of the four following operations should be carried out according to the conditions found on exploration

The sigmoid above the stricture can be joined

to the sound lower part of the rectum.

2 If the sigmoid is fixed so that it cannot be brought down the transverse colon if low may be anastomosed to the rectum and to the descending colon above the stricture

3 If this is not feasible the caccum may be joined to the rectum and the ileum joined to the colon above the stricture

4 The lowermost coil of the fleum may be joined to the rectum and by a lateral anatomosis to the descending colon above the obstruction

The difficulty in all these procedures is the application of the usual suture methods because of the

difficulty in commanding the rectum through an abdominal incision

The author has devised a means whereby these operations are rendered comparatively easy. In whatever segment the upper opening is made the small female end of a Hildebrand button is inserted and fixed with a purse-string suture. By means of an especially devised forceps the larger male end is pa sed through the rectum and made to project upward so that a small incr ion may be made over the central part which then protrudes allowing the bowel wall to slide down so close to the spring that no suture is needed The two halves of the button are then clamped. The result is a passage for facal matter into the rectum instead of outward on the abdomen or through the lumbar region while drainage of the large intestine is possible through this route E. L. IRESTROYC

Axtell W II a Acute Angulation and Flexure of the Sigmoid a Causatl e Factor in Epilepsy Tr im Partel Ser Detroit 1916 Ju e

In December 1910 the author published his first h t of 31 cases 8 private and 23 a ylum cases. In lugu t 1011 a further report was made on 10 private cases with a recoveries the included a ad bitional a ylum and a private cases making in all 36 cases. The 3 reported cuted have remained so

for a period of over four years. One additional case of the original list of 10 private cases has had no return of the convulsions since ceasing treatment two years ago The treatment seemed at the time to increase the irritation as reported.

Since the last report Axtell has had 9 additional cases with a of them remaining free from seizures for from one to two and a half years making in all

45 cases reported with 8 recoveries to date

From his observations the author is convinced that those who acquire epilepsy after the fifteenth year are more amenable to successful treatment than when the trouble commences earlier in hie. In his judgment surgery can give but little relief except where there is a definite history of inflamma tory adhesions holding the angulations and flexures in fact the condition of feecal stasis precludes surgery of the colon until the condition is first relieved which when so relieved eliminates a prime factor in the production of the trouble. A new and undescribed cause of the intestinal prosis which is so generally present in these cases is the separation of the recti muscles which are so essential to a thorough evacua tion of the colon and for the support of the abdom inal organs

The essential failure of treatment of these con ditions has in the fact that so few recognize the true condition, and if the condition is recognized there is not sufficient persistence in relieving the condition or an ignorance as to the amount of material the colon holds and as to when it is well emptied. As the result of failure to recognize the true condition mutilating surgery is resorted to without get ting results commensurate to the gravity of the sureery resorted to the first intimation of the true condition being found upon opening the abdomen then details are carned out which should have been used in the first instance and which would have rendered surgery unnecessary

Hawley D C.: Position for Sigmoidoscopic Work Tr Am Procted Soc Detroit 1916 June.

A majority of writers express a preference for the knee-chest position while a minority prefer some other such as the Hanes Sims or the exaggerated lithotomy position,

Refore the days of the pneumatic sigmoidoscope the position was of necessity such as would admit of inflation by atmospheric pressure. Here the knee-chest position was undoubtedly the most satisfactors

The Luce-chest position is trying and disagreeable for the patient and not easy nor always convenient for the operator. Its use is frequently attended with embarrassment and fear on the part of the patient

With the pneumatic tube the older m thod may be discarded. The author favors the following method

The patient is placed in the left lateral pro position with the left arm drawn out behin! the b cl the patient lying well over on the left chest and stomach, the knees flexed the right more than the left and placed above and well over and beyond the left on the table and with the back concaved as much as possible. In this position the abdominal muscles are related, while in the kneechest position they are apt to be contracted. In a majority of cases the instrument may be passed easily and quick ly over the brim of the pelvis and into the sigmoid colon as far a required or to its full lenth.

This method is not advocated exclusively but a

more thorough trial is urged.

Hanes, G. S.: Some Important Pathological Conditions About the Rectal Outlet. T. Am P. sciol Sec., Detroit, 9, 6 June

Tubercular ulcerations do not occur as frequently in the mucosa of the rectum and signoid as in generally believed. Amorbid and various types of bacterial ulceration produce dynamics expression that often lead to emaciation and exhaustion. Active tubercular ulceration is always accompanied by a decided increase in th temperature and pulserate. These are not characteristics in other types of ulceration. In tubercular ulceration there is alteroy of constant and progressive ympt ms while in amorbic there is usually a history of constant and progressive ympt im while in amorbic there is usually a history directly only the provenent and relapses. Tubercular ulceration involving the results and adaptional seldom yield a constant and produced and the constant and the

Bacterial types of ulceration are usually very difficult to treat. Within the last two years Hanes has found canterfraction with the high tension electric spa k to be a most valuable means of treatment

Theretian bost-set often occur about the rectum when patients otherwise show so evidence of the colosis. The abscesses and subsequent is tuke a colosis. The abscesses and subsequent is tuke are characteristic in that there is great tendency to underming of the skin. The external penings are therefore large with a filled piperance of the a reounding cutaneous structures. They point to impending tutaneous structures. They point to impending tutaneous structures. They point to great importance that direct the habits, hygiene, etc. of individuals thus afflicted.

Fixule of long standing with common very small external openings with history of an extensive becess are cry difficult tours. From external evidences they appear to be very simple. Usually the florer when i troduced well into the rectum will be able to detect by carried pulps thou the bard indurated sinuses which frem extend amortisingly high up by the rectum.

I ternal fistulous openings rarely II ever per forate the rectal wall unless there is some pathology primarily in the rectal nuisons whereby its resistance is impaired. The internal openings of the fistule are usually in the anal canal. The anal tissues are almost always diseased before the baces is formed, therefore it is reasonable to suppose that the infection passes out through the diseased anal structures and it repromishe for the absence.

There are occasional futulous tracts that extend up by th rectum t considerable heights and are very tortuous. It is difficult to follow these sinuses t their terminations when operating. When the wound heals and a mall open ig emains it is fairly certain that some part of the original fixtula was or reched. It is then advantable to infert

I runtus ani is undoubtedly a local infection. The focus of the disease is below the pectinate line and at the anal margin. It is seen the author's practice t remove the diseased tissues at the margin of the annus and from the emulsion of these diseased truct res bacteria are cultivated and an autorerous et e diministered to the natient.

bism th paste which will often effect a cure.

The operati with togenous vaccine obtained i this manner gives decidedly the best results.

Krouse L. J. Spasmodi Stricture of the Rectum.

7. 4m Proces Sec. D trust of June.

Spanned atrict re of the rectum is often called phantom stricture on account of it imaginary existence. Krouse t tes that in the arily part of the last cent ry it worse frequently diagnosed than later in At the reset time the opinion regarding the estate of f has affection is equally divided between those who are firm believers and those who doubt the critical.

After qu ting the t t ment of various authors well are tractal pathology he expressed his own oplians as t it fastence and reports several cases lie agrees with far writters he believe that passender stricture is often the forerunner of the more serious disease of benign tricture of the recetum. He reports several law.

krouse claims that spasmodic stricture is not a disease but only—ympt m of some other disease located in the rectum or in an adjoining organ His cond, soons are

It I not a common affection.

It is easily detected on digital examination.

It often terminates in an annular fibrous

3 It often terminates in an annular fibr stricture
4 It involves the lower Houston valve.

5 A rectal ulcer is the most important etiological

factor
6 Curing the ulcer in its early tare lessens the

chances of the development of an annular fibrous stricture.

Syphills, regarded as a contagion disease as

sypinus, reguled as a contagion disease as other exanthemats, is characterized by its chronicity and virulence. The only exception to its point of inoculation being confined to tissues covered by aquamous epithel um, is within the rect m.

Its frequency in the rectum and ansu is not real ised and, consequently is not recognized by the profession. Its relationship t fatule and stricture is emphasized, and the importance of tuberculosis in these two conditions minimized. The cressful treatment of situle is proverital. The possibility of stricture resulting from secondaries later in lifis suggested. Drueck, C. J: How to Examine the Rectum Chicago M Recorder 1916 xxxviii 280

A very careful clinical history should precede all examinations. The author includes an outline which he has found serviceable and which allows for a detailed history.

The examination comprises inspection digital

and instrumental examination.

Inspection reveals many points which might other wise escape notice Digital examination is the most important of all and should not be painful when properly executed A careful method should be followed in making the digital examination so that no false interpretation may result

Intrumental examination is made by bougies and specula. The former are dangerous to use and are not recommended. An ordinary bivalve speculum is usually satisfactory for an examination of the lower part of the rectum. A long conical speculum with an artificial light gives the best results in the examination of the upper rectum and sigmoud.

J II SETLES.

Yeomans, F. C.: Malignant Transformation of Benign Growths. T. Am Proceed Soc. Detroit of the

The benign tumors of the colon and rectum considered were of the polypoid type solitary polypoid in the polypoid similarly polypoids multiple adenomata and vil lous tumor. All ongenate from the intestinal mucosa areof the same histologic structure but differ in number size form and the relative amounts of glandular and fibrous tissue present.

The author dies the theories of origin of multiple adenomata as advanced by Meyer Liebert and Schwab and 4. Hauser and H. C. Ross a views on the formation of benign growths. Neomans thinks these tumors inflammatory in character and notes the frequent history of colitis or dysentery in these cases intestinal parasities as causal in others, and it the positive evidence of the rôle of irritation asfurnished by therapy—colonic lavage or colostomy and irrigation benching some patients and curing others. He reports a case of multiple adenomata in a man asset 30 colostomized in 1013 with marked benchin Many tumors have disappeared the re-mainder have retrogressed and the patient is working. There is no evidence of multiple annual change.

That being growths become malignant is beyond questin but the cause involves the same enigma at the cause of cancer itself. The author cities the work on nevolatins of Waldever (damit cathear and others, as well as modern research on the tran plantation of tumors and the parasitie theory of their origin. He concludes All that can be stated positively is that cancer begins as a small local proces. That it excites no reaction in the blood whereby a diagnosis can be made that the in lividual cancer-cell 1 the para lite of cancer and whatever excitable explains the origin of cancer will also explain the transformation of a benign into a real remain growth.

Seomans reports the transformation of a simple adenoma into an adenocarcinoma in a man aged 76 who had rectal bleeding of 8 years duration progressive constipation and a tumor that in recent years could not be reduced within the rectum. The tumor 3 5 by 2 inches was attached just within the anal verge. It was removed under local anaesthesia and both clinically and histologically was proved to be adenocarcinoma.

Villous tumor or adenoma tends to recur in malig

and radically

Multiple adenomata constitute the most important and senous type of bening growth of the intestine. Their usual site is the lower colon and rectum. Clinically they are multipannt from diar thesa, harmorthage etc and if neglected over 40 per cent become actually malignant. Improper local treatment as snaning curettage and cauter ization is followed by malignant recurrence in a large proportion of cases.

The curative operative procedure indicated is enterotomy either in the colon above the growths or in the terminal lieum when the entire colon is affected. If the tumors disappear the enterotomy may be closed. If they persist after prolonged irrigation and the patient a general condition war rants it partial or total colectomy is indicated with implantation of the ileum low down into the sig mold, the operation being performed either in one or preferably two stages.

Gaut S G: Anorectal Injuries. T 4m Proctol
Sec. Detroit 1916 June

While the rectum is protected by the buttocks and bony structures it is frequently injured by external trauma expulsion of hardened faces, and by foreign bodies swallowed or introduced through the anus such wounds being contused, lacerated incised or nerforated

Laceration of one or all of the rectal coats results from careless examinations introduction of imperfect syringe nozzles bougies proctoscopes, or other

instruments.

Perforating wounds are caused by bullets, knile thrusts and pointed objects that have been swal lowed or introduced into the rectum except when due to specific ulcers or cancer

Recently many pneumatic rectal ruptures, the result of compressed air introduced through the anus in a spirit of fun have been reported

The injection of carbolic acid into hamorrhoids is responsible for extensive anorectal injuries.

The chief manifestations of superficial anorectal injuries.

The chief manifestations of superficial anorectal injuries are bleeding sphincteralgus frequent mic tuntion and painful defection symptoms that are

exaggerated when the wounds are ext n is Infected wounds are characterized by a chill temperature throbbing pain an Iling and a thick

Jellow lischarge In exten i e injunes of the upper rectum harmor

than is prime The i shock the patint of

lapses and soon exhibits symptoms of pentonitis. when the peritoneum is involved. The diagnosis of anorectal injuries is easy when the nature of the accident is known, the degree of hemorrhage, bruising and swelling noted and the

buttocks, anus, and rectum inspected and digitally and proctoscopically examined. As to the treatment minor i juries take care of themselves, while extensive injuries may require simple or complicated treatment

Incised wounds are sutured under ascoti condi-

tions. Contused, lacerated, and poeumatic injuries are drained at one or more points, following irrigation. and the ragged edges and necrotic tissue removed.

Subsequently they are treated by drainage and topical applications, as fistula wounds Injuries of the bladder and urethra are immediately closed when fensible but if n t the bladder

is drained, and the wounds here and in the rectum are permitted to heal by granulation Small rectovesical rents are sutured, b. t where the

rectum or sigmoid is extend ely injured, the bowel is resected, or an artificial anus is established Rectovarinal tears are repaired by uturing the

vaginal before the rectal sid of the wound is closed.

Barnes, R. H. Observation on Flasure in Ano. T Am Procted Sec Detroit o 6, June

The author considers fissure as an ulcer and be lieves that traumatic causes re ot true etiological factors in the production of this trouble but that t is necessary that the timues become a flamed and hence (rail and easily torn in der that fissure be formed. He believes that catarrhal inflammatory conditions are frequently the result of an excessive carbohydrate diet and sometimes an

In the treatment of assure he recommends pallia tive treatment by correcting the diet with reference to the excesses of carbohydrates and fats and placing the patient on a proteid diet for a time operation is eressary, h believes that the blect should be drainage rather than paralyzing the muscular fibers. He also advocates the use of a mall enema before defecation i order t a rold irritation from the stool. It is very importa t t the wound clean by hot sitz baths and the hot enema, in order that any foreign batance may ot lodge in the wound.

Hill, T. C. Prolapsus Anl in Adults. T. Am Procted Sec Detroit, a o June,

The theory is advanced that all cases of procidentia recti are the result of neglect r improper treat ment of wh t was in the beginning a simple form of m cous membrane prolapse. Correction of the condition early may prevent senous infirmity later

He describes at length an operation modified after that of Goodsall of London. In this opera

tion h employs a multipl sut re. He advises removing the excess of tissue distal to the ligature.

The operation is performed under local anxithesia and is advised for patients of all area. It is particularly suitable f use in prolance of the aged The uthor claims that the operation is painless, short and easily performed. There is absence of hamorrhage and the end-results are satisfactory

Terrell E. H. The Treatment of Harmorrhoids by New Method. T Am. Prectol. Sec Detroit. o 6 Tun

The author presents a simple, safe and efficient method of curing selected cases of hemorrholds by th injection of quinine and urea solution. Dur ing the past two years 7 patients have been treated by this method with only one recognized failure. Injection of quinine and urea in solutions of from a to so per cent strength produces starys tion and atrophy of the hamorrhoids. The series reported includes only uncomplicated internal harmorrhoids. The results of the treatment of these patients justify the 11tho 2 conclusion that the method is simple safe, and effective in properly selected cases.

LIVER, PANCREAS, AND SPLEEN

Einhorn, M The Duodenal Tube as a Factor in the Diagnosis and Treatment of Gall Bladder Disease. J Am M Am 9 6 kvl., 903.

The duodenal tube has made possible the obtain ing of secretions direct from the papilla of Vater and th instilling of fluids in its vicinity Einborn has diagnosed probable cholecystitis by direct examina tion of the bile in forty cases. He co ciudes that in the majority of cases in which turbid bile is found in the duodenum in the fasting condition, cholecys titis with gall-stones exists. Turbid bile is occasionally found without gall-bladder disease, when the liver is seriously involved (neoplesms, or echin circhoels) or in stricture of the duodenum below the papilla. Exceptionally clear bile is associated with biliary calculi, either the gall bladder not being inflamed, regardless of the presence of stones, or the stall-bladder is entirely filled with calculi no bile entering the organ.

The macroscopic appearance of the bile is importa t a clear yellow bule denoting a normal function of the liver and gall bladder while a turbid, green ish, o dark brown bil usually means a diseased stat of one or both of these organs.

In a number of cases of cholecystitis an attempt was mad to instill either a weak solution of arreyrol or of ichthyol just above the ampulla. This treat ment is based on the idea that astringents will exert a beneficial effect on the bile-d cts. Infections of 20 to 30 ccm. of a 0.25 per cent solution of argyrol may be given every other day The improvement is often striking benefiting not only the digestive disorders but the gall-bladder condition. The author believes that duodenal alimentation finds an appropriate place in some forms of cholecystitis, partic ularly when complicated with ulcers of the stomach T. K. ARMSTRONG or duodennm

Deaver J B: Recurrence of Symptoms After Operation for Gall-Stone Disease. Illinois

During the period from January 1, 1910 to Jan uary 1 1916 1 031 operations upon the gall bladder or billiary passages were performed at the German Hospital with a total mortality of 7 18 per cent

The type of operation and the mortality of each is

shown by the following table

•	Operations	Death
Cholecystottomy	160	20
Cholecystettomy and cholecothostomy Cholecystostomy	14	4
Cholecystostomy	417	
	23	4
Cholecystostessy choledochostomy and part tostessy	700	
Chologystochandenostomy	35	4
Cholescoper	65	2
Choledochodradenostomy		
Cholecystogastrostoncy		
		_
	Α3	74

Mortality 7 18 per cent

During the same period and included in the above were 42 cases that had been operated upon previously for the same disease. Of these 5 had had two previous operations and one had been operated upon 3 times without relief In all 50 operations were performed upon these 42 cases. The onerative mortality in this group was exactly 8 per cent. The 4 fatalities were due in one case to un controllable hemorrhage in another to the same cause plus leakage from a cholecystoduodenostomy in the third from toxemia and exhaustion, and in the fourth which was the case mentioned as having had 4 operations death was due to acute nancreatitis and carcinoma of the head of the pancreas.

It would appear that gall-stones are the most common cause of the recurrence or persistence of symptoms after operation. They make their presence known within a year and often within a lew days or weeks. They are usually stones that have been overlooked or out of reach but if the gall bladder has been left the possibility of re formation of stones cannot be disregarded.

In 8 cases the cause of later trouble was either failure to dislodge infertion or a re infection of the biliary passages and pancreas Chronic and acute cholecystitis without stones was found in 3 instances

and chronic pancreatitis in s

The author feels that the percentage of failures from these sources would have been much higher had he not laid great atress upon free and long continued drainage of either the gall bladder or common duct or both in all operations upon the biliary passages. The use of maximum sized tubes which are allowed to remain until they practically fall out has been his rule. Operative biliary fistules always close if there is no obstruction to the normal passages and the physiological rest afforded by free drainage is of the utmost value in allowing the tissues to clear away the lurking infection.

Stricture of the common duct was met with in 6 instances. In 2 they could fairly be attributed to surgical treatment since in one the duct was ac cidentally injured during cholecystectomy and in another a severe local infection caused sloughing of a portion of the duct itself In the other 4 cases the condition was secondary to extensive and long continued disease of the duct such as suppurative and ulcerative cholangitis and might have been doctared refras vel he trivele

In a cases the only lesion that could be found to account for the symptoms was the presence of ad besions. It must be said however that adhesions often extensive and dense were present in all of the cases They are part and parcel of the healing process. It is a difficult matter to say just what part adhesions play in the production of symptoms Where they produce definite kinks or obstructions of the stomach duodenum or intestines it is not so difficult to correlate the mechanical conditions with clinical effects. The author does not disturb ad hesions when operating unless they are in the way As a rule they cause no trouble and if disturbed. they are sure to re form and probably more densely than before

More recurrences took place after simple drainage of the gall bladder than when it was removed Thus in half of the stone cases recurrence was due to calculi left or re-formed in the gall bladder. In one case stones were impacted in the cystic duct and would have been removed by cholecystectomy When stones are overlooked in the common or heratic duct it is, of course clear that the treat ment of the gall bladder is of no moment so far as subsequent obstructive symptoms are concerned. It is better to remove the diseased gall bladder when complicated by pancreatitis.

The causes of recurrent symptoms following op-

eration for gall stone disease are the following Late operation and extensive pathology Type of operation not adapted to the lesion Overlooking stones in the gall bladder or ducts.

Reformation of atones Persistence or recurrence of infection of gall

bladder, ducts or pancreas

Insufficient dramage. Adhesions, especially adherent duodenum py Jorus or stomach

Internal biliary fistula. External biliary fistula.

Contraction of papilla of \ ater Stricture of the common duct Stricture of the hepatic duct

Stricture of the cystle duct

Chronic pancrentitis pancrentic lymphangitis and interstitial pancreatitis. The type of operation done must necessarily

influence the result for example draining the gall bladder when it should be removed or vice versa draining the gall bladder externally when it should be drained into the duodenum I flure to drain wh n there is present a chol ngitis pancreatic lymphan

4 Recent surgical experiences in young children

aff rd clinical ba is for such hopes.

5. In view of the otherwise hopeless nature of the case the biliary tract should be evpl of as soon a the diagnosts is sufficie thy established and if the he and mind retailous permit — 16 per cent of published cases—an artificial peasage to the biliary of the control of t

EDWARD L. CORNELL

MISCELLANEOUS

Davis, J. D. S. Vaine of Pain, Jaundice and Tumor Mass in th. Differential Diagnosis of Discussion of the Right Upper Quadrant of Abdomen. T. 4st 4. Obs. & Gyacc. Indianapolis. 9. 6 Sept.

Th usual symptoms of peptic ulcer are pain, vomiting and harmorrhage the most import t of

which is pain.

Pain is the earliest definite symptom. It is usually aggravated by large amounts of food and often relieved by small amounts. Pain may come on during ingression of food but more frequently comes on a few hours after meals and at night Coatrie ukers are often characterized by periods of long remission instrumittency occurring for 1 ng periods of time during which the patient often

believes himself well.

The \(\) ray examination will often be a helpful aid in determining the presence of peptic ulcer. If the valuable information may be secured by the roem genologists, many of when claim to disgnose 75 per

cent of ulcers.

Pepike uleer diagnosis is usually based pon the presence of localized pain, followed by omiting, frequent presence of occult blood in gastne con tents or stools hypersecretion, increased amount of gastri cortents, rehable findings with the Y-ray and often hist ry of an old srrit ted dysperpike.

If morthagic panere titls is solden and violent in set is characterized by exercicating depseated pain usually in the epigantium or between the xiphold and umbilious associated with severe nauses and contilep hicrough, constipation, and

albuminuria frequently results.

Acute supportative panerealitis usually begins suddenly with sever epigastric pain, vocalting hic cough chills, and an irregular pwemi temperature and progressi e tympanitis.

In pancreatic calcult paroxysms of pain may be due to the impartion of store. The pain adutes alo g the lo er left costal border to the back rather than to the right side. Detection of free fat in stools or glycosuria may markelly sid in the diagnosis. Characteristic calculi found in the stool is confirmatory. Jau dice rarely appears in pacteatic lithiusis aless the stooe passes into the common duct and becomes lodged. If this takes place or if pressu e is male upon the common duct by inflammatory swellung jaundice m y oc

In cholecystims pain may or may not be cry severe, depending largely upon the amount of obstruction produ ed by the swelling i the ducts.

Epocastri pain with local soreness beneath the right rib marron is usu lly followed by nauses and romiting. When the common bile-duct is occided jamence with chilis and high temperature may tentit

result Renal calculus is accompanied with severe pain wh th stone gets int th kidney pelvi or ureter ins h position as t block th flow of urine pain radiates from the loan bliquely downward ato the right ilia region - the front of the thigh, blad d r o genital organs Symptoms from renal stone depe d pon the six chara ter and location of th The put may appea suddenly and is of an agonizing har cter associated with marked muscular rigidity or pastn. It the tone passes, pain may suddenly rease leaving the bladder more r less ritated. If the stone is rough t may produce much urnt two and harmorrhage. If the ureter remains long blocked by a tone hydronephrosis marked by tumor man ben ath the costal regio ma be found. When supported on occurs in connection with tone py ephrosis results and pus, blood cast and albumin may be tound in the unne, and sept symptoms may res lt

The h er when enlarged from hepatic abscess may be to all w rall cho below the rib border. When d t m ha other intections, dull achi g palms are present all over the bloomen. The pain is most act during the night or early morning. Indigential has been beauth be lassiful to cardet innigue and a foul breath may be present. Loss of appetitie weight, and oke may take piece and at times yellow kinn, and oke may take piece and at times yellow kinn, the present that the present his present the form the present his particular to the present his present the form and the present is afficient. I press out his life middles the justifier is slight but if the pressure is sufficient. For some more than the pressure is sufficient to the pressure is sufficient to the pressure is sufficient to the pressure is sufficient to the pressure is sufficient to the pressure is sufficient to the pressure is sufficient to the pressure is sufficient to the pressure is sufficient.

is will

Flanting kidn y pals is not so severe as that from renal store and is localized in the night side of the abdomen. If the ureter is deted or pressed poin by the de-sent of the kidney, pain will result. If a band of fascia or blood vewel is abnormally focated so as to dr a garros, site ureter in the kilney descent in a manner to obstruct the ureter the pathent may saft pain fast be foin which may be projected down along the et r. When the it chments are foose enough it admit free mobility of the kildney the ureter is not liable t. kink and the kildney remains yright midst.

Nephromata or hypernephromata cannot often be distinguished from floati g kidney. It is usually tender to pressure but unaccompanied by pain. Nephromata may or may not be associated with sex

chnormalities. In appendicitis the pain in a large number of

cases occurs at the engastrium and then is diffused over the abdomen and generally localizes at or near McBurney's point If the appendix is long enough to extend into the region of the gall bladder and ducts its inflammation may excite symptoms of cholecvatitis or choledochitis and the pain may be at the rib border If located behind the caecum pain may be referred to the loin or to the right rib margin. If in contact with the ureter the pain may simulate that of renal stone. Regardless of its location it is often the cause of gastro-intestinal dusturbances - pylorospasm, hyperchlohydria, and general intestinal irritation. Appendicitis is usually accompanied by temperature, high or low fact in acute attacks elevation of temperature is the rule. Its existence is often doubted when other symptoms are unaccompanied by temperature. Nausea and vomiting are usually present in all of these conditions but are not significant or especially characteristic.

Taundice is a valuable diagnostic sign. It appears in appendicates and renal disease only as a result of

sepsis.

Obstructive cedema due to a duodenal ulcer near the ampulla of Vater sometimes results in a closure of the common bile-duct and may cause nancreatitis

and laundice.

Choledochuta and cholelithiasis are accompanied by slight or marked jaundice which may be of an intermittent or transient type. It may be so slight that an examination of the conjunctiva or a chem ical examination of the urine is necessary to de

Pressure by pylone cancer upon the common duct may give rise to jaundice of a constant progressive

intense type.

Peptic ulcers both of the stomach and duodenum are at times so infiltrated as to cause a tumor mass that may be felt in the median line or heneath the right rectus muscle which is at times very tender to touch Pylone cancer produces a tumor that at times is freely movable upon full inspiration and is separated from the costal margin by a distinct depression. They are usually far advanced when palpable — firm irregular often palpless and not very tender to pressure.

When the gall bladder is disturbed from obstruc tion to the cystic or common duct it produces a pear shaped tumor mass at the margin of the liver movable synchronously with the diaphragm and presenting no depression between the rlb margin and

the tumor mass.

Appendiceal tumors may be located anywhere in the abdomen. They are sometimes six or more inches long and may become attached to any other abdominal organ. When inflamed they may become fixed by adhesions to some surrounding tissue.

Floating kidney tumors are usually marked by smooth, sharp outlines and mobility usually free from pain and tenderness unless obstruction results from ureteral pressure.

A hydronephrotic or pyonephrotic kidney is usually stationary or fixed well back into the loin and does not move with the diaphragm. The hydronephrotic kidney usually presents no urinary findings while the pyonephrotic kidney is usually accompanied by septic symptoms the urine showing blood, pus, albumin, and casts.

Pain is the most prominent symptom in all condi tions of the right upper quadrant and is of great value in a differential diagnosis if the peculiarities and characteristics of pain common to each condition is kent in mind.

Regardless of every aid in diagnosis it is often difficult to differentiate and instead of waiting months or years for the trouble to clear up an ex ploratory diagnosis under nitrous oxide gasoxygen or novocaine should be made

Penk, J H Viaceroptosia, I ter at J Surg rtlx 103

The author's principal aim in this paper is to show the development of operative procedures for the relief of visceroptoess. In so far as the morbid entity and what might be termed the medicinal treatment may be concerned every physician ought to be perfectly familiar with these features therefore, the author deals briefly with the surgical phase of the subject in concluding his paper

The extent and character of the existing pions will necessarily determine the surgery to be under taken. The rule the author follows if the patient is a relatively good surgical risk, is to first perform nephropexy then place the patient on the back and open the abdomen in the median line above the umbilious abrade the upper surface of the liver with a gause sponge shorten the round ligament of the liver plicate the gastrocolic ligament and anchor the colon by attaching the greater omentum where it comes off the colon to the abdominal wall at about the normal level of the colonic position. (This last procedure the author has performed many times during the last ten or fifteen years.)

Following the operation the patient is placed in bed with the foot elevated ten or twelve inches. This position is necessary in order that adhesions may form properly about the Lidney and liver exceedingly light diet is maintained and the bowels kept open by enemas rather than purgatives. The patient should be maintained in this position for twenty-one days but can be shifted slightly from side to side to change the center of gravity and thereby give the parts rest. At the end of the third week the foot of the bed may be lowered to the normal level and the patient will be able to leave the hospital at the end of the fourth week.

SURGERY OF THE EXTREMITIES

DISEASES OF THE BONES, JOINTS, MUSCLES TENDONS, CONDITIONS COMMONLY FOUND IN THE EXTREMITIES

Cunningham, S. P. Regeneration of Long Bones Following Infection True 34 J Med 0 6

The author considers the methods of treatment which have been of most value in treating infected long bones resulting from compound omminuted fractures. The principles to be kept in mind are (t) the general condition f the pats at () the injured member should be placed in as TLIA S DOL mal position as es be maint ined without i ter ference with the blood supply by sand bugs and e tension (4) when infection i severe bot moi t ppli cations should be made t th part t promot dra n are and a splint applied under the limb to f cilit to the changing of dressings Probing m nipulat n. and irruration should be olded. After i fection is controlled the utbor uses the Moorbol was to dry fill the cavity. He has reached the concl. si that bone regeneration is the result of the combined action of the periosteum and blood-cl t Tw cases 11 # # 1COL are reported.

Cameron, II C.: Osteogenesis Imperfecta. Proc Rey Sec. Med 19 6 ix, Sect D Child 43

A case is reported of this rath rare bo condition in a child aged five years

The author makes these three been tions () Osteogenesis imperfects is a condition ha tertized not only by deficient ossification and framity of th long bones, but also by a typical and pecular for matin f the skull which consists f bulging the temporal region sufficient to displace the upper part of the ear () The shortening of the limbs is more marked in the proximal than in the distal porti as of the limbs. Charact ristic expansion and the tort ous, sinuous outline of the haft f the long bones are noted. 11 // // LL

Remy C. E. Bi Scientiles Their Relation t Multiple Fractures in Childhood. If d C = cll 0 6 xxl 11

The author traces the heredity of blue scierotics or osteopsathyroids, and finds that with on exception the co dition of fragil bones was transmitted by the females and occurred nly in the males. He also finds that in addition to the fragility of the bones and the blue sclerotics, in all cases presenting bi scierotics, there is an accompanying flat foot and a peculiar tendency of the I wer eyelid t cover the lower portion of the iris. He thinks the con dition is due to a congenital deficiency of the matter furnishing the bones their elasticity

Moore J L.: Osteomyelitis Involving the Hio-Joint 4nn Sure I bila. 1016 Irii 473

Eighteen years ago the author denounced the use of the term epiphysitis as applied by most writers to an acute inflammation of the hip-joint believed then that the condition was one of acute osteomy elitis and subsequent observation has con firmed his opinion that the condition does not arise in the epiphysis, but on the shaft side of the bone. The term epiphysitis was suggested by Macnamara because of the ranty of ostcomychtis in this loca tion and the absence of a diagnosis until the epiphy sis had become senarated. The name osteomyelitis as applied by the author is not strictly correct as the neck of the femur has no medalla but the process resembles esteomyelitis in every other particular and demands the same prompt treatment. When the diagnosis is made very early before the joint is involved an incision should be made over the greater trochanter and an opening drilled through the trochanter and the center of the neck of the femur in its long axis until the seat of the infection is reach ed. When the diagnosis is not made until the joint is involved it is better to open directly into the joint from the front. When a late operation is done, a

neck should be preserved for future use Four cases are cited as proof of the correctness of the author's contentions. All of them occurred in children under twelve and all involved the neck some with and others without loint involvement He suggests that it might be well to revive the old term "acute osteltis of growing bone." GATEWOOD

formal excision should not be made unless the neck is completely necrotic, but as much as possible of the

FRACTURES AND DISLOCATIONS

Compbell W F: Colles Procture Med Times 10 6 xli 16t

The author gives a detailed discussion of Colles fracture. He contends that the reasons for imperfect reluction of these fractures are largely a lack of apy reciation of the fact that the fractured frag ment are locked impacted and must be disengaged before they can be normally replaced. In order to accome hi hithis anasthesia for securing complete relaxation is essential. Colles fracture is not an of ce fracture " it is a hospital fracture and if the fragments are accurately reduced retention is ca ily accompli hed with almost any kind of splint R. B Courts

Seralim C: Isolated Fractures of Head of the Radius (Sulla fractura Isolata d'I capitello del

Pure isolated fractures of the radius are comparatisely rare. The author gives a short historical review of the subject from Verneuil's memoir in 1551 down to the present time. He divides tranmati lesions of the head of the radius into the three to owing classes

Fractures which involve the head alone either complete or incomplete

. Fractures which involve both the head and neck of the radius in which the direction of the line of fracture injures the mass of the head for a much greater extent than the neck complete and incom plete. These are fractures of the head radiating

to the neck

3 Fractures associated with the head and neck. so-called explosive fractures in which the fractured diaphysis at the level of the neck supplemented by the continuation of the traumatizing action in directly in the head of the radius which is broken into several fragments. In this variety fracture of the neck is primary and of the head secondary

The author gives short histories of 57 cases gathered from the literature and adds fuller details of 7 personal cases which he has observed in five years. In 22 cases the injury was caused by a fall on the palm of the hand with the forearm in flexion In 28 cases the injury was due either to a fall on the elbow or to the elbow striking some hard object

Generally such fractures are more frequently due to direct than to indirect trauma. The etiology mechanism pathologic anatomy symptoms diagnosis, surgical and non-surgical treatment as well as

the results are discussed

Clinically such fractures are recognized by the tumefaction and the pain localized to the external part of the elbow under the epicondyle by the limi tation of movements especially of pronation and supenation and by the dislocation and malposition of the fragments Clinical examination should in variably be supplemented by radiography of the elbow in different positions.

Mobilization and massage may give good results but if there are free articular fragments and the head is badly dislocated early operative intervention is called for The latter gives excellent results and is preferable to late intervention. It is indicated generally when callus formation is noted The ultimate results as to functional value cannot be stated until at least a year has passed after the injury With free fragments the ultimate prognosis may be PTRVC. W A. BRETTHAN

Jones R: Malunited and Ununited Fractures. B # M J., 1916 1 809

The author states that conditions to which the terms delayed union and non union are applied may be difficult to distinguish becau e there is often found even after months osteogenetic changes lead ing to consolidation in a fracture considered to be permanently united. There may be several weeks of apparent inactivity in callus formation and then consolidation occurs quite rapl ily Delayed union is the most common in the mildle of the femur in the humerus at the junction of the middle and upper third and in the tibis and fibula at their lower third.

A fundamental principle in the treatment of fr c tures is to secure and maintain good length and good alignment and in securing these en is care should be taken that the circulation of the limb should be in no way impal ed.

If a case of delayed union is first seen in the seventh or eighth week it is necessary to do no more than make q ite sure of good alignment length and circulation.

For old cases Jones recommends the percussion and damming" of H O Thomas which consists f breaking down the soft fibrous callus, turning the

fractured ends toward the skin and beating them with a mallet A pulley i then applied t the limb and extension produced. A Thomas knee-spli t is adjusted and the extend a maintained. Two pieces of rubber tubing re tied around the limb no three or four inches above the fracture the other an equal distance below. At first they re kept on twenty minutes each day later on several hours at time They should be tight enough to cause considerable awelling and stasis.

In aseptic compound commi ted fract res Jones strongly recommends that the pieces be saved the pieces are quit loose they should be taken out laid in alcohol and carefully replaced in postion or around the site of fracture

Weak union on be diagnosed by t signs (1) tenderness on pressure over the ut of fra ture

(s) exuberant callus xudation.

The best in thool in fract re treatment is that which requires the least skill to carry out rather that the tipe elaboration of surgical technique. R G P CKARD

Flint J M Treatment of Fractures by Methods of Suspension and Extension. 4 Phila o 61 il 64

Lapecial attention is called to the 1 of xten sion when combined with aspension in fracture It is necessary in this kind of treat trestment ment that there be some sort of iron frame firmly t tacked t the head and foot of the hed and five feet bove it surf ce to give movable points of support with adjustable pulleys. With proper adjustment the best methods are easily determined for suspension f sample fractures. f doing pointess dressings i such cases a compound fracture of the el

bow or for complex appliances for badly complic ated fractures. The addition of a spring in the line of pull as a shock absorber is a wonderful source

of relief to the patient

In fractures of the humerus the extension can be vertical homiontal or angular and in cases just above the elbow this angle of the arm and forearm can be varied several times during the day to avoid ankylosis formation, and meanwhile the patient can

sit, lie or sleep

Suspension of the lower extremity is variously used. In fractures in good position hammocks may be used allowing the patient to rotate the limb. For tibial and fibular fractures requiring extension and for supracondylar fractures the railway splint with the self-contained extension apparatus may be used so-called because the lower fragment rides upon a carriage that tracks on the main part of the splint while countertraction is obtained by adhe sive plaster over the upper fragment attached by a helical spring to the splint. Subtrochantence cases need the Hodgen splint Fractures of the femoral neck require the Hodgen splint with foot extension.

SURGERY OF THE BONES, JOINTS ETC.

Harrison, F C. A Splint for Drop-Wrist Canad Pract & Ret., 916 xfi, 191

The author describes an easily constructed splint by Southerland to be used in the treatment of in juries to the musculospiral or median nerves from which drop-wrist results.

A posterior splint for the hand and arm is made of several layers of plaster-of Paris bandage three or four inches wide with a thin piece of board, one and one half inches in width, running longitudinally nearly the length of the plaster Three more lavers of plaster bandage are applied above the board and then strips of flannel are placed across the splint for the purpose of fastening it to the hand and forearm. Two more layers of plaster bandage are then applied to secure the flannel strips whole is then moulded to the back of the hand and forearm extending from the base of the fingers almost to the elbow. It is allowed to dry and is then cut across at a point corresponding with the wrist joint and hinged the board embedded in the plaster holding the screws firmly A spring is then attached by metal uprights to the hand and the forearm pieces. In this way the wrist is held in a position of dorsal flexion. Flexion can take place to the extent of allowing the hand and forearm to come into line R. B COTIELD

Rich E. A. The Treatment of Abscesses in the Course of Tuberculous Disense of Joints and Bones. Northwest Med. 1016, 17 237

The author pleads against unnecessary and dangerous incusion of tuberculous abscesses pointing out the harmlessness of the collection and the possibility of back pressure having a real function

In his opinion, the only indication for any opera tic procedure is such an increase of abscess pressure as to cause intolerable pain and then the only procedure that is justifiable is aspiration under the most ingrouss ascepts. Aspiration is indicated to relieve pressure and not to evacuate the cavity and in old chronic cases where the disease itself has subsided. Aspiration should be done with a No. 13 of 14 wire needle and not with a trocar. The author has had small success with the use of Beck's paster.

Ridlon, J. As to the Secessity for Operation in Joint Tuberculosis. Chicago M. Recorder. 916 xxxvin 256

The author reports (wo cases of tuberculosis of the knee joint treated by conservative methods. The first was an adult female whose right knee-joint following a fall upon it, became tuberculous and was excised with a resulting anks) losis.

Subsequently the left knee became inflamed and was examined by six eminent surgeons all of whom diagnosed it as tuberculous. Conservative treat ment by immobilization, for three years resulted

in a cure with a normal range of motion,

The second case was in a girl five and one-half years old. The left kine was seen after being in flamed for a year and was treated by the application of a brace. During the course of the treatment five sumes opened up and discharged for many months. In three years the knee was cured in a straight position and in four years the knee could be completely flexed and the patient walked and ran without immong.

Exercion should never be done in children. In adults it is a time-saving measure but one half such cases require amoutation later on H W without

Belot and Filhoulaud: Osseous Repair and Proliferation (Sur la réparation et la prolifération osseuses) J de radiol et d'électral 19 6 ii, 87

Radiologic study of osseous traumatisms of warshows that apart from those which cover spontancously there are many with a different evolution. There may be an exaggerated osteoperiosteal proliferation. The neoformation may take the form of a voluminous callus surrounding or immobilizing a foint or involving the muscles, and the functional importance engendered may be such as to require surgical removal of the expressions.

The callus formations observed in peace are quite different from those observed in war. The latter are large extensive rich in elements rapid in ossi fication often proliferating at quite a distance from the point of fracture. This is accounted for by the fact that the subjects are young and in full cellular activity. There is an abundant production of fragments more or less grouped and disseminated and almost always accompanied by debra of perforterm and thus latter constitutes the reparatory nucleus. These periosteal fragments scattered here and there even in the neighboring muscles continue

to live and proliferate, and multiplying their elements not only forms a voluminous callus but even an exaggerated one with distant osseous trabecules.

Traumatized bone ordinarily shows a marvelons tendency to reparation the tendency of separated bone and perfoxed fragments to five exists even when radiographically they appear deprived of all relation with the body of the bone. The author thinks that a certain amount of reserve abould be exercised in the removal of all bone fragments shown by the radiograph. Only those which are manifestly incapable of living should be the object of an inmediate removal. These will comprise fragments without perforteum, infected fragments, fragments without perforteum, infected fragments, fragments without perforteum, infected fragments, fragments other fragments the later clinical of radiographic numifications will surgery what must be removed.

While it goes without saying that infective phenomena will necessitate an immediate wide cleaning of the wound it about he borne in mind that it is necessary to allow the bone sufficient elements to permit of reparation. Frequently absence of consolidation results from a too radical removal of

bony debris.

It is more important to remove the fragments t a distance which are usless for reparation and which can act as foel giving birth to osseous formati na.

The authors cill particular att then to the value of radiologic examination not only in the diagnosis and study of fractures but for the determination of high particular particular to the physicotherapeutic treatment if rh restoration of innetion. Clinical observation alone cannot always give sufficiently accurate information as to diagnostic them to the properties of the property of the properties of the properties of the properties of the particular them as well as the imperfection of consolidation.

W A. Brenfan.

Delagenière H. Ostropsetostic Grafts Taken from the Tibla to Serve in the Reconstruction of Bone or in the Repair of Loss of Oserous Subtance (Des grafes outcopénosiques prises tible pour serve à la réparation des prites d'substance osecuse). Bull et séas. Sec d'chir d'Per 9 6 s'ili, qu'à

Delagensker given details of at operations in military service in which thial gratis have been used with good results. In bis cavil practice before the war the poor results which had obtain efform oneous gratis, properly so-called, forced him to resonance them in favor of esteoperiotical gratis taken from the tibia. The tibia is easily eccessible, and its internal face is large and extensive so that there is ample material for a graft. Moreover repair of the osseous wound left after removal of a graft is facile even if the graft is thick and the medul lary cavily of the bon pen.

He finds that autografts are best and therefore confines his practice t grafts taken from the patient's tibia and generally for the following class of cases (1) pseudo-arthrones of the arm forearm, or tibia, (s) for the stoppage of loss of bony substance and (3) in autoplastic operations of the nose. The result of such grafts is uniformly good. The technique of centing he graft and applying it in the different classes of cases is described fully. The evolution of the graft is different in infected and non infected cases. In a septic or pursuing wound the phenomena are rather complex. The perioticem grafts in this conduit on the the ose-cost parts of and become necroit. Frature are stabilized which beal only when the climination of the necrotic secons parts is complete. At this time the graft can be radiocopically observed to be transparent, but by degrees it becomes oney a and theseforth behaves as in the resolution of a such septic graft, and the such second parts in this case the evolution is much above.

The author draws teention to the efficacy of this species of guit in cranial injures where there is a very extensive loss of substance. Many of the cases reported are of this class. On croot of its simplicity and fficacy he thinks it indicated in all cases of important loss fernatial home and even in minor losses when the subject shows signs of meningeal limit tion. W. A. DERSHAM.

Brown, W. L., and Brown, C. P. Important Points in Bone-Transplantation. Tran St. J. Med. 9 6 mi, 3

Th authors report their conclusions reached from expenimental work does with bone and periosteal transplants, their cault agreeing with those of the maj rity of investigators. They were unable to reprod ce bo e from periosteal transplants, eith rice o left att hed, cept from a bone where train ma as necessary to it removal, that is, only bone and bone-cells reproduce bone. Bone transplanted free int. the tissues, either with o without perios teum is live just bos bed.

Bone when transplanted must be in such a position that t has a function t perform, must have sufficient to t ct with living bone and sufficient immobilization t secure primary union.

Clineally the graft sho ld not be too large should be planted within the old periost um, if possible hould be required to maintain but httle mechanical support, and there should be complete smoothlization for several weeks. The graft in locations in which there is continued liability to displacement, requires dditional internal mechan ical support

All the periosteum t the point of contact should be preserved. The technique f the bone work should be f ultless. IL W WILCOX.

Lyle, H. H M The Aperioateal Stump and Its Care, A Serg Pints 0 6 hill, 674.

In amputations there are four methods of treating the bone osteroplastic, tendinoplastic, periodical, and aperiodical. The latter while the simplest and most practical is the only method most likely to give an end bearing stump. The technique consists in removing thoroughly a small cull of periodicum, o 5 cm. in depth, and a posoning out the mar

row cavity for a like distance If shreds are allowed to remain they are liable to produce painful bony

spikes

The stump should be quickly put to use. As soon as healing is accomplished massage is instituted twice daily and a 2 per cent solution of salicy lic acid in olive oil is rubbed in. The stump should then be pressed against a box in the bed five to ten minutes, three times a day and this pend rapidly increased. Standing exercizes are soon begun and at the end of two weeks the patient should be able to wear a peg leg R. G. PACKARD

ORTHOPEDICS IN GENERAL

Henderson, M. S. The Intraperitoneal Inoculation of Animals Its Diagnostic Value in Orthopedic Surgery Am J. Orth Surg. 1916 xiv.

In a series of 143 patients tested by the author guinea pigs were used in the majority of cases. As the guinea pig is rather resistant to the bovine type of tuberculosis while the rabbit is not Hendersen recommends that where the patient is a child there fore more likely suffering from a bovine type of in fection the rabbit or both rabbit and guinea pig should be injected.

He concludes as follows

1 As a test the intrapentoneal inoculation is practicable and requires no special laboratory facil lites. The test has been of great value in doubtful cases, and in instances in which it is possible to obtain the material for inoculation it has become a routine procedure.

2 A positive bacteriologic test in obscure lesions makes the diagnosis certain

3 The value of negative tests increases with the number made

4 Antiformin digestion of tissue acts on the tubercle bacilli either to kill them or to reduce their virulence so that the low resistance of the guinea pig will be sufficient to overcome them. It greatly reduces the value of the test and should not be used.

Partice Lewis

Vulpius, O: Experience with the Albee Operation for Spondylitts Tuberculosis (Erfahrungen mit der Albeeschen Operation bei Spondylits tuberculosa) Muracken med Webstek 1916 Irlii 546.

Aulpius gives the results from his orthopedicclinic in Heidelberg of the Albee operation for tuber culous spondylitis. The operation so far at least as end results are concerned is little known to German orthopedius plants as reexamined 24 operated patients and reports have been received of 6 others who were operated upon. Moost two and one half years have elapsed between operation and the reexamination. The ages of the patients varied from 3 to 45 years the majorits being under 10 years. The typical Albee technique was used

In all cases there was easy and uneventful recovery except in 3 cases where some bony splinters had to

be removed. After the operation there was a remarkably prompt cessation of subjective phenom ena. Pain ceased after a while and the patients could easily move about Anatomic preparations made a year after operation are instructive and show that there has been a firm union around the graft and that the graft has been absorbed. All the subsequently examined patients may be considered to be clinically cured. One child died after a year of tuberculous meningitis and this was the only death. No case complicated with paralysis was operated upon and Vulpius has seen no paralysis develop after an Albee operation. In 7 cases in which there was a psoas abscess before operation this process was resorbed. As a result of his ex perience Vulplus strongly recommends the opera tion. W A. BREIDIAN

Wallace C.: The Operative Treatment for the Disabilities and Deformities Following Anterior Pollomyelitis. Am J Orth Surg. 1916 xiv 400.

The author bases his article on a study of the oper ations at the Hospital for Ruptured and Crippled Children during the past three years

He states that the attempt to secure anly losts of the hip in children by doing an arthrodesis has been hopeless

He thinks that nearly one third of the operations performed in the series would have been unnecessary if the patients had received proper brace atten

The Soutter operations for contractures about the hip are most beneficial

The transplantation of an active hamstring tendon when both were normal, to the attachment of the paralyzed quadriceps extensor tendon so improved the power about the knee that braces have been discarded.

Arthroderis for paralytic deformities in children has been of little value.

The grooving of the tibialis anticus tendon into the anterior surface of the tibia and transplanting the extensor proprius hallucis tendon to the cakaneoscaphoid ligament for equinovalgus deformity has been helpful

He found the typical Whitman operation the most satisfactory for calcaneus calcaneovalgus and dangle foot deformity Pritter Lewix

Davis G G: Stability of The Lower Extremity in Paralytics. Am J Orik. Surg 1916 xiv 391

The author states that in treating paralysis the pmme object is to secure support and secon larily to promote propulsion to the greatest extent possible. Stability is therefore the first consileration intimately associated with stability is the question of balance. Stability has largely to do with hones and ligaments but balance is largely controlled by the mu cless.

If what the author calls the suba tragal r joint is the only invol ed part the li ability i oft n not marked and ther are a number of wors to tal like

In the order of efficiency he names rthrodesis. firstion of tendons, tendon-transplant tion, and allk ligaments.

The ankle-loint is close to the subastragalar joint and the paralysis most frequently produces toe-drop or less often a culcaneus. Even a will laced abou may prevent a shight toe-drop from being trouble some. If the case is more severe the foot may be held up by fastening the extensor tendons or the peronel and anterior tibial to the terior part of the tibia. In the cases of calcaneus usually assoclated with cavus, G lli buries the t nd into the tibia postenorly St tic problems of the foot are comparatively easly solved without the

use of apparatus. If a t ble lower ext emity is to be obtained one must f vor the assumption i the knee ad hip joint of hyperextension. He can secure a 1 bl ball knee by fixation of the ankl joint plus an levated

heel When the muscles controlling the hip of running from the trunk to the fem especially the el tena madmus, are paralyzed the difficulties re greatly increased. If the eluteus maximus is acti e then even if the quadriceps femoris is paral zed, the gl tens will pull the femur back and frequently hx the knee but in hip paralysis the disability is often extreme.

Where extreme external rotation is n esent it can be controlled by the operation of sewing th f ada lata firmly to the post ri edge of the greater trochanter while the foot is beld tirm internal retation. PRILLIP LEWIS

Withard D P Subastracalar Arthrodesis in Lateral Deformities of Paralytic Feet J Orth Sure o 6 1 5

The operation recommended be the the co gists of an arthrodesis of not ally the astragaloacanhold, but also of the astragalocalcancal rticula tions, and in severe cases of arus perhaps the calcaneocuboid joi t as well It is more than ar throdesis it is the weldlig together of the drouning surf ces of three bones, the astragalus scapbuid and or calcus. There is no careful dissection if the cartilaginous joi t urfaces. Instead there is a rough diering and gourng of both the articular reas, and also the bo y surface between them, with no ttempt

t removal f the fragments that are torn loose. The astrugalus scaphoid and os calcus become one solid bony mass, movabl in th anteroposterior directions but immobile for side movements sh rtening of the foot occurs. A rigid point of trachment is given to the unpuralyzed muscles. No foreign substance is left in the tissues.

Two incisions re recommended one on the inner side of the foot about a fingerbreadth below and in front of the internal malleolus on the level f the austentaculum tall the other on the outer side im mediately below the external malleolus.

The foot is fixed in plaster t right angles to the ler The patient is allowed to walk in the cast at the end of fou weeks, and the cast is removed four weeks Unless the paralysis of the other portions of the leg demand it no braces are applied.

Taylor R. F Operative Treatment of Infantile Paralysia. Am J Orik Surg 0 6 to 304

It is the uthor belief that tendon sutured to tendon is not so efficacions as tendon sutured to persosteum or bone preferably t the insertion f the paralyzed tendon it is to replace. A muscle to be transplanted and to functionat most successfully must have its tendon pull in as straight a lin as possible from its origin to its new insertion.

No allk extension is comparable in result to plan-

ning and effecting an operative procedure so that there is ample tendon to reach to the new insertion

Adhesions in the transplanted tendon are to be avoided by carrying it through subcutaneous adipose tissue through the sheaths of tendons that are to be replaced or through septa in which non-clossible forming have been made by plastic flaps and by early electrical stimulation to prevent adhesions from forming Several small skin incisions are preferable to two large ones. Subcuticular silver stitches are less likely to lead to adhesions.

The question of time when weight bearing is to be permitted depends upon the seventy of the original deformity the strength of the transplanted tendon and the security of the mechanical fixation by stuties the possibility of early muscle training in active exercises electricity massage etc. Weight bearing should not be permitted sooner than 30

days and then with some support

Fine intestinal silk is preferable to catgut langa roo tendon or heavy or parafin-coated silk in su turing the tendon accurately to the penosteum in the bone groove Prints Lowin

Ryerson E W: Methods of Stabilizing the Fiall Foot in Infantile Paralysis. Am J Orth S rg

The author advises more frequent resort to as tragalectomy in the feet which are very weak and in addition a fixation of the tendons by the Gallie operation slightly modified

Whitman's operation of astragalectomy and back ward displacement of the foot is of great value in the treatment of calcaneus deformatics. Arthrodesis has a distinct field of usefulness in patients over fourteen years of acr.

Silk ligament suspensions may have to be removed or the foot may relapse and it is extremely difficult to control lateral deviations of the foot by this

Rycron was unable to get good results with the autogenous bone per or dowel driven through the lower end of the tibis and through the satragalist and or calcia. For six months he used the Gallie method of inlaying the tendon in the groove gouged in the bone and in addition to this drilled a hole through the bone at the upper end of the groove He then dissected up the proximal portion of the tendon cut off as high as possible passed it through the hole and brought it down in loop-fashion to be sewed side by side to the portion lying in the groove.

Anderson W. L.: New Methods Used in the Study of Flat Foot at Yale. Med Times 19 6 xli 144.

Methods of diagnosing static foot troubles and their correction as carried out at Yale University are given by the examiner the author

There has been added to the equipment of the medical office the most modern form of apparatus for making a diagnosis of faulty foot conditions. This apparatus consists of a wooden table 36 inches high with a top surface 20 x 26 x 2 inches in which is sunk a 13x13x 25 inch plate glass section. Seven inches below and fastened by hinges to the rear legs of the table is a 13 x 22 inch German silver reflecting mirror which can be adjusted at varying angles from 30 to 45 degrees to the plate glass in the top of the table. Clutches on either aide of the frame holding the mirror enable it to be fixed at any one of these angles which adds to the comfort of the examining physician. On the sides and fastened to the diagonally opposite legs are electric lights with 15 watt frosted globes set in aluminum lined reflectors so arranged that their rays are thrown directly upon the glass top convenient distance in front of the table a long mirror 20 x 54 inches, which is also adjustable is placed so that the patient is able to see the bottom of his own feet as he stands upon the glass-topped table. In this way the physician as well as the patient has an exact picture of the actual degree of foot fault while the feet are maintaining the weight of the body and photographs of the foot condition can be taken if desired. R. B Comeld

Jones, R. The Soldier's Foot and the Treatment of Common Deformities of the Foot, Brit 11 J. 1916 1 782

In the treatment of hammer toe the author ad vaca against amputation particularly if the affected toe is as is usually the case the second toe for this removal is likely to cause the development of hallux valigus. Arthroplasty is not advised. The operation advised is a wedge-shaped excition removing the articular cartiliage on both sides of the joint so as to definitely ankylose the joint in extension. An oval piece of skin, including the usually present corn, is excased and the flexor tendon is cut and the toe put up in extension on a little splint. This splint is worn for some weeks to insure ankylosis in the extended position.

In displacement of the little toe the displacement is similar to that of hallux valgue. Amputation is the treatment advised. A good-sized disp is necessary to overcome subsequent contracture. If a callus is present over the head of the metatarsal walking with a shoe is not permitted until the callus has softened up and the skin becomes more nearly normal. Only very exceptionally should the head of the metatarsal be removed also for this forms one of the points in supporting the foot on which a soldier's matching power depends.

Metatarsalgia is a peculiarly painful disability of the foot associated with flattening of the transverse arch. Immediate relief Jones says, can nearly always be given by removing the pressure of the body weight off the heads of the metatarsal bones by a bar behind them placed transversely across the sole of the shoe bringing the weight bearing on the neck of the metatarsals. The linr side of the hele of the shoe should be raised one-third of an inch and a band of strapping placed around th

transverse such of the foot. In cases of losses standing not responding to this treatment the head of the metatarsal, usually the fourth should be removed. The same type of shoe should be employed as after-treatment

Painful conditions about the heel may be due to (1) injuries or strains about the insertion of the tendo achillis (a) anurs of bone and adventitions burse under the os calcis, (1) osteitis and periostitis from

direct I jury of the os calcis.

For Group : the method of pin-firing used by the farrier is advised in the more obstinate cases where rest and elevation of the heel three-fourths of an inch does not relieve. This condition may be due to inflammati n of the hurse or train in the I sertion, but in both c ses the treatment outlined I the me A band of strapping of ced in t above the malled is beneficial

In Croup a Jones a letses an Inchion long the inne margin of the heel d the removal of the put

and the adventitions burse

In Croup & the esteitis and percetitis may be al ght and rest usu lly cures these but if they are a sociated with a gros it cture of the os cald of astragalus of any severity the solfi will not aguin be fit for service M S H you un

Elmer W G The Handling of Child en with Tuberculoris of th Spi Whill They Are Under th Influence of an Angesthetic, 1 s. Swr Philato 6 lti 14

The author cites two cases from his own experi ence which show how important the self-protection offered by the muscular system is in cases of tuber culosis of the spine. In children, especially the relaxation of the patient und r a general anath tic makes it very easy by slight torsion by stretching or by increasing the kyphod to do great permanent damage. In one of the authors cases he believes that tuberculous material was forced into the spinal canal. In the second case in attempting to push the child further down on the table the spine was buckled like a binge

Since it has been shown that children bear boxegrafting into the spine very well, and that the results are very satisfactory great care should be taken to prevent such accidents as the aboy as very little violence is regulred in this type of case. The enth or suggests the application of a cast on the day precedling the operation. This cast is split on both sides in the midsxillary line and the following day the bild may be pla ed upon the t ble and the anterior half removed. After it is thoroughly angsthetized 1 m y be turned to the pron-position, a thout danger f jury t the spi e and th pietenor part of the tremoved. CLINICAL ENTITIES — TUMORS, ULCERS ABSCESSES, ETC

Hazen H H: Cases Illustrating the Faulty Treat ment of Superficial Malignancy J Am M An 1016 levi 1810

During the past three years the author has been consulted by 32 private patients for malignant con ditions of either the skin or mucous membrane of the mouth. Of this number only 6 consulted him for early untreated stages of cancer. One of these had a cancer on the under surface of the tongue while the remainder had cancer of the face.

The faults in handling the other cases naturally eroup themselves under three headings (1) neglect on the part of the patient (s) faulty diagnosis on the part of the physician and (1) improper or in sufficient treatment by either physicians or quacks. In o instances patients had neglected themselves without seeking medical advice. In this series there were 6 cases that had been wrongly diagnosed by the attending physicians and 12 cases were either improperly or insufficiently treated after a correct diagnosis was made. In several instances more than one faulty method of treatment was employed a cases had been treated by caustics spatients had operations performed from which rapid recurrences took place. One small basal-cell lesion of the cheek had been treated by fulguration with a recurrence in nine month the recurrence being both deep and I ur of the patients had been treated by small livided doses of roentgen rays. method f single dose therapy had been in use such a short time that we have not as yet had a chance to study recurrences after it although some will doubt

Special interest attaches to a serie of 4 ca es which were treated by the much younted radium all of the patients being made much worse. The conclusion are

t. The public is not yet sufficiently educated as to the importance of attending to superficial sores that will not heal

While it mu t be admitted that seme cases of superical malignancy are difficult to diagnose still entirely to many of them are mistaken for other affects in even by expenenced physician. All superious growths should be positively diagnosed at once.

- t. Many cases are not treated radically enough It so hild always be remembered that in all comtreatment of whitever kind is the worst possible thing for a patient suffering from a malignant condition.
- 4. Radium even in large dose, and when admin tered to reed its grates, alwayates, then mar infals? ein the superial, a est that to belevel to architecture. The sink tax to

McCouch G P., and Ludium S D W: Is Myopathy Related to Disorders of Internal Secretions? Med Rec 1916 ixxxix 1042

Myotonia congenita and myasthenia are frequently associated with muscular dystrophy otonia congenita is said to have occurred in connec tion with muscular dystrophy and may be identical with one form of it. There is some evidence sug gesting that thyroparathyroid deficiency may bear an etiological relation to myotonia Myasthenia is frequently associated with hyperthyroidism hypo-adrenalism and probably with hyperactivity of the thymus. Hypothyroidism and pathological findings suggesting both hypo- and hyperactivity of the thymus are sometimes found in amy otonia My opathy is found in association with many disorders of internal secretion perhaps most frequently with hypopituitansm The case reported by the authors combines the adiposity the deficient development of both primary and secondary sexual characteristics the small hands with tapering fingers and the enlarged sella turcica of dystrophia adiposo genitalis with the distribution of atrophy and pseudohyper trophy proportional muscular weakness diminu tion and in some cases total loss of tendon reflexes and the diminished response to electrical stimuli without reactions of degeneration characteristic of the fascio-scapulohumeral type of progressive muscular dystrophy

Abderhalden tests on a series of four cases of my opathy one case that may be either my opathy on explain muscular atrophy one case of neuritic muscular atrophy (peroneal type) and two cases of muscular atrophy from syphilitic root neuritis showed hyperactivity of thytoid thymus and adrenal in the first three conditions. In the personeal ca. e hyperactivity of the tests was also noted. The tests on the syphilitic cae were negative. Thyroid and thymu hyperfunction are frequently observed in hypoptulatin im.

Whether the glan lular disorders bear an etiological relation to myopathy or are secondary to it or whether both are due to a common cause is uncertain but the combination is too frequent to be resarded as a mere coincidence

SERA VACCINES AND FERMENTS

For II II: Vaccine Therapy and Other Treatment in Acne Vulgaris and Turunculosi J in M II 1/10 It 2/4

A study of the examination records fith entring student at Corn II to restly howeld hit yoo per cent of the freshmen lass uffered from a new part of this propertion the distribution of the level not be great to

In order to ascertain just what results could be expected from the different forms of therapeuris, and more especially to try out the efficacy of vacrine therapy an analysis of too u selected cases of these two forms of pyogenic lermatoses was under

taken.

The cases were all considered chronic, in that they were all of six months du ation and no case was I cl ded in which the eruption could possibly be ascribed t drugs to occupation r to yphilis. ttempt was made to study the bacterial etiology ol either condition except in so far as was necessary for the preparation of the autogenous vaccines, since that has been so well worked out by previous in restigations and also because ordinarily the stock receives are prescribed on the ba is of a clinical diagnosis.

All the patients studied were instructed, be fore beginning treatment to avoid such foods as seemed to divagree with them, not to eat to excess to eat slowly and at regular i tervals, to drink plenty of water especially on rising I the morn ing to see that the organs of elimination were functioning normally or if they were not to consult the physician in charge before resorting to medical corectives. Locally they were to remove the come dones by gentl massage after first having relaxed the skin by pplications of towels wrung out i hot we ter Following the removal of the blackheads. they were t apply to the f ce towels wrung out of rold water in order to tone up the skin and cause a diminution in the size of the pores

In the tables given the most striking point and one not generally brought out by writers on the a blect was the fact that in the 74 cases of arme treated not one of the cases developed in a student engaged in athletics. The author does not mea t imply that acre has pever occurred in athletes but he wishes to point out that the table shows the great part thictics plays in the preve tion of sone the other hand howeve nine cases of furunculosis, out of a tot I of 26 occurred among student engazed in athletics. These cases were due t direct infection and without exception or urred among the wrestler and crew men the location of the leston being typical of the cause of the troubl

BLOOD

Marriott W. M. A Method for the Determination. of the Affail Reserv of the Blood Plasma I & Int Med 9 0 11.81

M rnott poi t out that bies bonates, alkali protein ompounds, od small quaptities of Ikali phosphates together - natitute the alkali reserve of the blood-plasma and that nir normal conditions. these substances are present in very cousta it quan titles. A dimin tion in the alkali reserve kno n as adost and may be recognized by lini al symra ma and by chara teristic alter those the omposition f the blood urine and al voluair

The alkali reserve maintains the plasma at a cont at lightly lkalla reaction do not the fact that cil prod ci of metabolism re continually being poured into the blood. Chief among the cid prod ucts so far as total q antity is concerned 1 (a bonic acki. This, as earboard tide nters the plasma cir. culating through the tissues and is taken in partly in combination and partly as desolved carbonic

add. An almost infinitesimal change in reaction in the direction of addity occurs. The slight change is sufficient to attinulate the respiratory center. The resultant pulmonary ventilation removes the excess of carbon dioxide and the plasma reaction returns to its original point. An excessive production of carbon deoxide in the tissues results in a greater change in the reaction of the plasma with a consequent increased stimulation of the respiratory center and increased pulmonary ventilation. This tends to accomplish the removal of the extra car bonic and. No depletion of the alkali reserve occurs

The author carried out a series of experiments on a large number of normal individuals and the method he employed consisted in dialyzing serum or whole blood against salt solution in order to remove color ing matters and proteins. The hydrogen ion con centration of the dialysate was determined by means of the indicator phenolaulphonephthalein phosphate solutions of known hydrogen ion concentration being used as standards for comparison At the out set of this work it was realized that the actual hydrogen ion concentration was not determined the results however coincided closely with those obtained by the electrical method. In severe acidosis variations in the direction of acidity were encountered. The method seemed to indicate variations in the hydrogen ion concentration although the variations observed were probably greater than those actually occurring

Also a series of cases exhibiting clinical or labor atory evidences of acidons was studied. These cases included nephritis and diabetes in adults and nephritis recurrent and idiopathic acetonomia and severe diarrhora in children and the results are recorded in detail

Briefly Marriott summarizes his paper as follows 1 Acidosis implies a diminution of the alkali re serve of the blood plasma though not necessarily a change in its hydrogen ion concentration.

2 A simple and rapid method for the measurement of the alkalı reserve is described. It is a modification of the indicator dialysis method for the determination of hydrogen ion concentration but is more accurate and gives more information than that method.

3 The method serves for the detection and ac curate quantitative estimation of the degree of acid osis

The results obtained in twenty five cases of acid osis are reported George E. Bettay

Leopold J S and Bernhard, A.: The Non Protein Nitrogenous Constituents of the Blood and the Phenolsulphonephthaleln Test in Children Am J Dir Child 1916, xi 432

The authors report the results of the examination of the blood of so children free from renal disease and of 16 children suffering from renal disease. In every instance the amount of the total non protein nitrogen of the urea nitrogen, of the uric

acid, and of the creatinin was determined. In the children free from renal disease the average of the total non protein nitrogen was 28 mg per 100 ccm of blood the average of the urea was 12 mg per 100 ccm, the uric acid average was 13 mg per 100 ccm. the creatinin average was 15 mg per 100 ccm and the average phenolsulphonephthalein excretion was 70 per cent

Cases suffering from some renal affection were divided into four groups acute nephritis chronic nephritis passive congestion and one case of sar coma. The phenolsulphonephthalein excretion was diminished in each condition while the non protein nitrogen constituents were increased only in chronic nephritis being within normal inflits in acute ne phritis being within normal inflits in acute ne phritis and in passive congestion. In the case of sar coma of the kidney the non protein constituents were normal with the exception of the uric acid which was increased.

From a study of their findings the authors concluded (1) that in children the blood content of the non-protein nitrogenous constituents is normally practically identical with that of the adult (2) that the variations under conditions of kidney affections correspond with those changes observed in adults under similar conditions and (3) that the determination of the non-protein nitrogen in the blood of children will prove as valuable a help in diagnosis and prognosis in children as it has in adults

J W TURNER.

Goodman C. and Bernstein E. P.: Presentle Gangrene-Thrombo-Anglitts Obliterans. V F II J. 1016 ci., 1073

The authors who believe the etiological factor of thrombo-angiitis obliterans to be an infectious agent, report 21 cases in which serological studies were made with regard to typhus fever

They call attention to the fact that thromboanguits obliterans is more prevalent in those coun tries where typhus fever is epidemic and they suggest the possibility of the specific micro-organism of tryphus fever being the etiological factor of thrombo-anglitis obliterans

The agglutination reactions and complement fixation tests upon the 2r cases were made according to the methods described by Olitaky In 18 cases the reactions were negative in 3 cases the reactions were marked one showing almost complete agglutination in a dilution of 1 200 and two in a dilution of 1,400

The positive reactions were given great weight because 102 controlled cases gave a negative reaction and because in many instances the serological reactions of typhus patients may become negative within so short a period as five months from the termination of the disease J W Trance.

EXPERIMENTAL SURGERY AND SURGICAL ANATOMY

Dubois, E. F: Membolism in Exophthalmic Goiter Arch. Int Med 1916 xvii, 915

In contrast with the symptoms on the part of the nervous system, the heart and eye symptoms which vary greatly in this disease, an increased basal me tabolism was found by Dubois with great regularity in exophthalmic golter which in severe cases he states reaches a level found in no other condi tion. On the other hand, in cretinism and myxocdema he found the metabolism lower than in any other diseases. The administration of thyroid extract particularly in myxcedema, raises the heat production. All other diseases in which metabol ism is increased are easily distinguishable from exophthalmic golter and they never approach the extremes found in this condition. The basal metabolism is higher than normal in youth, in fever in lymphatic leukemia, and in pernicious anemia, in severe cardiac disease and in some cases of severe diabetes and cancer It is lower than normal in old age and in some wasting diseases and perhaps in some cases of obesity Diseases of the ductless glands other than thyroid show in some cases an in crease in some a decrease but these are compara tively small

From the author's experiments and observations in a large series of cases he was able to make the fol-

lowing summary of his work

The metabolism in exophthalmic gotter has been studied for the first time in a respiratory apparatus which is also a calorimeter. Thirty-seven observations were made on eleven patients with this disease and six experiments were made on a cretin. With some of the patients the nitrogen balance was also studied.

The measurement of the heat production gives the best index of the severity of the diseases and of the effect of treatment. Very severe cases show an increase of 75 per cent or more above the normal average severe cases 50 per cent or more and mod erately severe and mild cases less than 50 per cent while a few mild and several atypical cases or those in which operation has been performed may be with in normal limits. In severe cases the warmth of the skin and sweating can be accounted for entirely by the necessity for the increased elimination of heat At lenst a part of the tachycardia is due to the in creased metabolism, and perhaps it might be possi ble to reproduce the extreme tachycardia, the car diac enlargement emacation, and mental irrita bility if it were possible to stimulate the metabolism of normal men for twenty-four hours a day over a period of months or years.

The specific dynamic action of protein and of glucose is within normal limits and there is no consist ent difference between the effects of protein in meatand an equal amount in milk and egga. One patient was able to derive 80 per cent of his caloriea from carbohydrate in an experiment when he was showing an alimentary glycosuria. There is evidently no interference with the oxydation of carbohydrates.

The methods of direct and indirect calorimetry agree very closely when the technical difficulties are connidered. The method of direct calorimetry gave results which were slightly lower than the indirect the total difference being 2 o per cent the average difference in the individual being 4 i per cent. This and the absence of abnormal respiratory quotients show that the law of the conservation of energy holds good in exophthalmic goiter and that there is no profound disturbance of the intermediary metabolism.

The average water elimination through the skin and lungs in the severe and moderately severe cases of hyperthyroidism is 39.9 grams per hour. The increase above the normal is closely proportional to the increase in heat production 25.7 per cent of the colories are dissipated through vaporization in golder patients whereas the mean normal is all most the same 23.9 per cent.

The level of the heat production was used as an index of the effect of medical treatment. Reat in bed for a week or more caused a drop of more than ro per cent. The effects of treatment with Beebe serum, thyroid residue, ergotin, and quante hydrobromate was less marked, each being tested on one patient. Ligation of the thyroid arteries with three out of the four patients studied caused a distinct rise in metabolism the duration of which was uncertain. There is as yet no proof the author states that any conservative form of treatment causes a greater reduction of metabolism than men tail and physical rest.

One small cretin 36 years old produced about half the calories eliminated by children of his size. As estimated by the surface area, his metabolism was about 20 per cent below the normal adult level. Three and a half days treatment with thyroid ex tract raised his heat production to normal.

GEORGE E BEILBY

Dewey K.: Experimental Hypercholesterolæmia Arch Int Med 1916 xvil 737

The author has made use of a watery colloid emulsion of cholesterol for intraperitoneal injections in rabbits and guinea pigs Instead of Merck s pure cholesterol he used a preparation obtained from gall-stones by extraction with ether in the Soch let apparatus. For the separation of all saponifi able substances from this ether extract, a method was employed which is based largely on Kumagawa and Sutro Five grams of the dried ether extract were dissolved in 350 to 400 ccm of petroleum ether to this 70 ccm of a r per cent absolute alcoholic solution of potassium hydroxide and 30 ccm. of dis tilled water were added. The mixture was shaken and the ether solution of cholesterol separated from the alcoholic solution of soaps in the separating funnel. The petroleum ether was evaporated and the dry cholesterol treated in the sam manner a

ficial vein by means of a Brewer or Pope tube The time during which the blood was permitted to flow has varied greatly depending upon the size of the tube used, the donor a blood-pressure, his heart rate, the physical condition of the recipient and the

symptoms which developed during the procedure The hemoglobin of the patients has been frequently recorded during the process of the transfunion and has been found to increase from ot 40 per cent while they were on the table. If n subsequent bleeding occurs the hemoglobin is generally from 5 to 30 per cent higher on the following day

In none of this series has any of the surgical accidents occurred, such as embolus, local infection. hamolysis or over-transfusion with its train of symptoms, or cardiac dilatation, cedema of the lungs tender tense abdomen, enlargement of the liver and spleen, and runture of the abdominal viscera. In 3 cases, immediately after transfusion the patient developed a severe chill and high temper ture. The temperature however subskied in about

twelve bours.

Where the time would permit, the examination of donors consisted in taking the history physical examination, Wassermann reaction, hemolytic tests and blood examination, with particular reference to leucocytosis, lymphocytosis coslnophilia, para sites, etc. It was not possible to make all of these examinations in nine of the emergency cases. Under these conditions relatives of the nationts were al ways used as donors and no harmful results were observed from the transfusions. In o e case the blood transfused was from the patient a son, and had previously been tested in the ordinary way yet this patient developed the most marked reaction in the form of a chill and fever of any of the series.

The cases transfused t minimize surgical risk were quite satisfactory The cases transfused for diseases of the blood, although showing slight bene fit, were on the whole unsatisfactory Cases transfused for shock demonstrated the value of this pro-

The author believes that there is no excuse for a surgeon permitting his patient to die from shock or hemorrhage without giving him the advantages of transfusion. Transfusion should be looked upon not only as a method f r reviving moribund cases with hemorrhage and shock, but also as the best prophylactic in preventing these conditions in individuals who are amende, depleted, and weakened by disease. Many after transfusion are enabled to withstand major surgery ALERET EXPLORATED

BLOOD AND LYMPH VESSELS

Villavicencio Treatment of Accessibl Arterial Aneurisms (\ota sobre el tratamient d los aneurismas arteriales accesibles) Gec mil é Caracas 9 6, relli, 64.

The author discusses the comparative merits of ligature and radical extirpation. He refers t six cases which he operated upon. Two cases of aneur ism of the carotid treated by ligature and 4 cases of aneurisms in the limbs treated by extirpation i.e., one of the superficial femoral, one of the popliteal, one inquinal and one axillar

The two carotid ancurisms recovered perfectly without complication. In the femoral ancurisms, gangrene developed and the patient died. The other three limb ancurisms recovered perfectly but complete nd radical extirpation of the aneurom alone was extremely difficult on account of adhecions etc.

The author believes that the radical cure of access-This art rial a curisms ought always to be the meth od of choice, unless there are special contra-indi W A. BREWNAN

SURGICAL DIAGNOSIS, PATHOLOGY AND THERAPPUTICS

Sibler W R. The Treatment of Scats. Praditueser Lond a 6 scvl 617

The most frequent causes of scars are injuries, surgical operations, burns, tuberculous and other ulcerating skin diseases, acne, and variola. Scar tissue, because of its avascularity is not affected by drugs taken internally, but may be locally influenced by physical and electrical agents.

Hyperemia with Bier's suction cups will improve depressed, irregular and adherent scars and tend to convert avascular int vascular tissue. Scarring from both acne and smallpox is benefited by this treatment. Other methods of increasing hyperemia are the use f radiant heat, moist or dry bot air and bot or cold compresses, all of which are serviceable for the relief of pain and for the production of hypersemia.

Massage is most useful in freeing adherent scars from deeper structures.

 Desquamating agents, such as salleylic acid. r resorcin from 5 to 30 per cent strength, may

be used to smooth down raised scars.

4. Electrical treatments, of which there are sever al forms, often give satisfactory results. By means of ionization soluble drugs are driven into the scar timue Sodium chloride, sodium salicylate, and iodine are the drugs used. Small repeated doses of X-rays may be cautionaly used on hypertrophic scara, especially if they are keloid in nature. Ra dium also causes scars to become amouth and mov able and reheves pain. High-frequency currents may be given locally or generally Galvanism restores the tone of adi cent muscles and thus in creases movement of the parts.

Of drugs used locally there are two (1) fibrolysin, which consists of a 15 per cent solution of combined thiosinamine and sodium salicylate, 40 minims of which may be injected every two or three days into the gluteal region or around the affected those and () deatricine (thiosinamine and antipyrine) which is stated to be non-toxic and non irritating, the dose for injection being from 8 to 17 minima. F. K. Ansternoon.

EXPERIMENTAL SURGERY AND SURGICAL AWATOMY

Dubols E. F: Metabolism in Exophthalmic Golter Arch Int Med 1016 Evil 015

In contrast with the symptoms on the part of the nervous system the heart and eye symptoms which vary greatly in this disease an increased basal metabolism was found by Dubois with creat regularity in exophthalmic golter which in severe cases, he states reaches a level found in no other condi tion. On the other hand, in cretinism and myxœ dema he found the metabolism lower than in any other diseases. The administration of thyroid extract, particularly in myxordema, raises the heat production. All other diseases in which metabol ism is increased are easily distinguishable from exophthalmic gotter and they never approach the extremes found in this condition. The basal metabolism is higher than normal in youth, in fever in lymphatic leukaemia, and in permicious anæmia, in severe cardiac disease and in some cases of severe diabetes and cancer It is lower than normal in old age and in some wasting diseases and perhaps in some cases of obesity Diseases of the ductless glands other than thyroid show in some cases an in crease, in some a decrease but these are compara tively small

From the author's experiments and observations in a large series of cases he was able to make the fol

lowing summary of his work The metabolism in exophthalmic goiter has been studied for the first time in a respiratory apparatus which is also a calonmeter Thirty-seven observa tions were made on eleven patients with this dis-

case and six experiments were made on a cretin. With some of the patients the nitrogen balance was also studied

The measurement of the heat production gives the best index of the severity of the diseases, and of the effect of treatment Very severe cases show an increase of 75 per cent or more above the normal average severe cases 50 per cent or more, and mod erately severe and mild cases less than 50 per cent while a few mild and several atypical cases or those in which operation has been performed may be with in normal limits. In severe cases the warmth of the skin and sweating can be accounted for entirely by the necessity for the increased elimination of heat At least a part of the tachycardia is due to the in creased metabolism and perhaps it might be possi ble to reproduce the extreme tachycardia, the car diac enlargement emaciation and mental irrita bility if it were possible to stimulate the metabolism of normal men for twenty-four hours a day over a period of months or years

The specific dynamic action of protein and of glu cose is within normal limits and there is no consist ent difference between the effects of protein in meat and an equal amount in milk and eggs. One patient was able to derive 89 per cent of his calories from carbohydrate in an experiment when he was showing an alimentary glycosuria. There is evi dently no interference with the oxydation of carbohydrates.

The methods of direct and indirect calonimetry agree very closely when the technical difficulties are considered. The method of direct calorimetry gave results which were slightly lower than the indirect the total difference being 2 o per cent the average difference in the individual being a 1 per cent. This and the obsence of abnormal respiratory quotients show that the law of the conservation of energy holds good in exophthalmic goiter and that there is no projound disturbance of the intermediary metabolism.

The average water elimination through the skin and lungs in the severe and moderately severe cases of hyperthyroidism is 39 9 grams per hour increase above the normal is closely proportional to the increase in heat production 25.7 per cent of the calories are dissipated through vaporization in gotter patients whereas the mean normal is al

most the same 23 9 per cent

The level of the heat production was used as an index of the effect of medical treatment bed for a week or more caused a drop of more than 10 per cent. The effects of treatment with Beebe s serum thyroid residue ergotin, and quinine hydrobromate was less marked each being tested on one patient. Ligation of the thyroid arteries with three out of the four patients studied caused a distinct rise in metabolism, the duration of which was uncertain. There is as yet no proof the author states, that any conservative form of treatment causes a greater reduction of metabolism than men tal and physical rest

One small cretin 36 years old produced about half the calories eliminated by children of his size. As estimated by the surface area his metabolism was about 20 per cent below the normal adult level-Three and a half days treatment with thyroid ex tract raised his heat production to normal

GEORGE E. BEILBY

Dewey K: Experimental Hypercholesterolæmia Arch. Int Med., 1016 avil 757

The author has made use of a watery colloid emulsion of cholesterol for intraperitoneal injections in rabbits and guinea pigs. Instead of Merck s pure cholesterol he used a preparation obtained from gall-stones by extraction with ether in the Soch let apparatus. For the separation of all saponifi able substances from this ether extract a method was employed which is based largely on Kumagawa and Sutro Five grams of the dried ether extract were dissolved in 350 to 400 ccm, of netroleum ether to this o cem, of a 1 per cent absolute alcoholic solution of potassium hydroxide and 30 ccm of distilled water were added The mixture was shaken and the other solution of cholesterol separated from the alcoholic solution of soars in the separating funnel. The petroleum ether was evaporated and the dry cholesterol treated in the same manner a

Auer J and Gates, F L: The Absorption of Adrenalin After Intratrucheal Injection J Exp Med 1916 xxill 757

In order to subject a living organism to the systematic action of any soluble substance, it is obvious that the substance must first reach the circulating fluids of this organism from the lymph and blood atreams the drug may then pass into the tissues and exert its effect. The main routes available for bringing any substance into contact with the tissues are as follows (1) by introduction into the gastro-intestinal canal (2) by subcutaneous intramuscular untravenous or intraspinal injection (3) by inunction through the skin, and (4) through the respiratory tract.

Auer and Gates purpose in this paper has been to test the possibilities of the respiratory route and they have submitted evidence of an experimental nature which shows that a simple intratracheal in jection of a solution in a normally breathing rubbit penetrates within a few seconds to the alwool chiefly those of the left lower lobe that absorption is rapid and well manutained and that the procedure may be repeated effectively a number of times even with a substance like adrenalin which decrease absorption. It was also shown that absorption of adren alin from the lung could be obtained at a time when double the dose given intramuscularly exerted no blood pressure effect whatever and that absorption could still take place after the development of pulmonary ordems when there was an undoubted dilution of the injection solution with a serum-containing liquid and when a diminution of the absorptive field had occurred.

The solution injected after reaching the alveoil is probably largely taken up by the empllanes of the pulmonary veins. This is indicated by the great rapidity with which an intratracheal injection of adrenalin may cause a rise of blood pressure. In numerous instances for example the pressure began to rise less than five seconds after the completion of an injection, equaling and even surpassing in rapid ity of effect intramuscular injection. Absorption by the lymphatic probably plays a secondary part, assumption rendered all the more likely when it is considered that lymph nodes are interpolated in the lymphat pulmonary path, where the bed of the lymphat pulmonary path, where the bed of the lymph stream becomes greatly widened and the current slowed.

Injection into the lungs, however offers another advantage due to the vascular arrangement of the absorbing field which could be of value therapeutic Absorption of liquids injected into the lung probably takes place largely through the capillaries of the pulmonary veins to a slight extent possibly through the capillaries of the bronchin veins which empty partly into the pulmonary veins, partly into the azygos veins, and probably some absorption occurs also through the lymphatics. By far the larger por tion of the absorbed material will thus be rapidly delivered to the left auricle and then to the left ven tricle. At each succeeding systole, as long as absorption continues, a fraction of the drug will be driven into the coronary arteries and be able to affect the musculature of the cardiac pump This fact the authors state, ought to render the procedure of intratracheal injection a valuable method when it becomes imperative to stimulate a suddenly failing heart as promptly as possible by drugs of the dicitalia group.

Intratracheal injection is perhaps better under the conditions mentioned than the intravenous route, for the surface veins cannot always be entered with promptness and certainty even under fairty normal conditions and in cases of cardiac weakness the difficulties will be measurable increased while an intracheal injection can be carried out with east. Moreover the authors state it is legitimate to expect that some absorption will take place from the lung alveoli as long as the heart lung circulation persists no matter how feebly and that thus some

tissue cultures had been obtained from this animal. During the prevent experiments 31 animals were used and a total of 50 operations were performed. The process of wound healing was attuded at rarious stages both in the living numals and in the preserved material.

The experiments reported in the present paper demonstrate that is wounds made in the skin of adult from there occurs as has previously been show to be the case in livi g cultures of adult from tissues, a direct transformation of the fibran-clot into a new fibrous tissue without any intracellular ction. This newly formed fibrou to ue whi h hills the wound space is apparently identical in prearance, structure function, and staining reactions with regularly formed permanent con ects e tissue It differs from adult connectl to tissue in the kin of the frog in its reaction with pancreatin digestion Ho ever this test as well as all others that ha so far been tried, fails to differentiat between th new f brous than and young connective tissu found in t dooles of various tages

In experimental wound made by removing various aired places of skin f om the f og the is rapid congulation of the blood plasm of diymph to form a coagulation tissue which fils the wound

cavity

Observations on lift gaminals show that the coagulation this e becomes more and more reastant,
and is generally of sufficient strength t hold the unedges of the wound in place and to tent position
in the wound eavilt. It serves, at least tempor
liary as a connect we thank and as base for the
rithelial cells is high rapidly move in from all the cut.

edges and cover the wound. The study of the prepared sections of wound tissue show that at heat in the orgulation tustic f rmed as a result of the dotting of blood and lymph a typical fibrin net is present in the wound. Later this fibrin net is transformed into new fibrous tissue containing bundles of a y fibers in which in many instances the indi adual fibrils can be noted. This transf rmation of the clot and the formation of the new fibrous tissue takes place before the tissue-cells wander into the coagulation tissue and therefore cannot be due t an intracellular action. It is a direct transformation f the hbran-clot and is identical with the process which was previously found to take place in the fibrin-clots in hving

cultures of adult frost thace.

The tissue cells, which later m int the new fibron tissue in large numbers from the surrounding are, 4,0 not dignst the bleep b: parently by their movements, cause a division of the large bundle, int smaller ones. These cells whe they first appear in the abroess tissue are ounded, but later they assume the typical longsted spladle shape of abrobiant cells. The preparations do not show any connection between these spirial shaped cells and the fibers which had already formed, nor in there any cridence of a later attempt by them to

form new abers intracellularly

The taining reactions of the new fibrous tissue of the con ective tas e in frog kin. However the new tastie can be digested in pancreatin and in this reaction; it dilets from the connective tissue in the six of the dust frog On the other had, steed—by engine the with pancreatin on mbryonic but fully formed connective tissue obtained from the tail and skin of tadpoles of arious get, show the transcreatin will digest it just as it does the owly formed horonat te. The direct beervation of the living essels und rying mechanical, thermal, electrical and bemical onditions has received comout I welv little attent on

The the xperim is a re-dose mainly on the frog using principally the merentery and the reag it imply of were dissolved no 575 per cent sails not too and applied by means of magicant be in any rubber bulb at me not and the other of a out into a moderately fine capillary. He post to detail the reaction observed by the

use fulkalies and of cideol tions.

Summing p his results the utho seems to be fully onescoust hat there still emain sufficient resollems that have not been solled and discrepancies that have not been solled and discrepancies that have not been reconciled. The curiously unrea and sparrently irregular contraction of the ascular sails, which they call beading demands furthe investigation and explanation, be believes.

The f ct that cleaning the meantery with filter or himes paper in one manner causes no disturbance hat-over and that again will ent constrictions may follow the sum manipulation, though suggesting se crally usible hypotheses, has a timered aprecase vilantion in his option. S milarly it has often been observed that sock solutions (allastine not so I cqu ulty) had appare thy no effect until the meanetery was washed with normal sail when the constrictions promptly appeared. Here again, he

states, several explanations suggest themselves, but

all these problems await further investigations Nevertheless it is believed that certain conclusions may safely be drawn from his observations furnish a further corroboration of what may now be accepted as a fact that there is in the words of Bayliss a complete chemical regulation of the cardiovascular system which may act independently from the central nervous system. It has been shown in this paper that it is not only the blood circulating in the blood vessels that takes part in the regulat tion of their functions, but that the chemical condi tions of the tissues and fluids surrounding the blood vessels also exercise an important influence. It appears furthermore that it is not only the products of the internal secretions which are concerned in this, but that common acids and alkalies the specific metabolites of the tissues and cells besides a number of neutral salts under ordinary circumstances for eign to the organism, may exercise a controlling in fluence. Strong acids act like alkali in compelling vessels to contract. It is true that such extreme chemical changes as have been presented in this paper are not ordinarily likely to occur Rown tree and his associates estimate the hydrogen-ion concentration of normal human blood plasma as varying from pH=7.4 7 6 of the blood serum from pH = 76-78. In chinical acidosis pH = 73.71 and in dogs just before death from experimental acidosis pH = 6 o. Henderson has shown that the blood is able to dispose of considerable quantities of alkali or acid without much change in its reaction. There must necessarily however be a limit to this and one may conclude from the observations recorded by the author that besides the chemical and physical reactions of the blood itself there are other chemical and physical factors which when once a certain limit has been overstepped may lead to grave disturbances of circulation, and one can easily conceive of certain pathological processes such as inflamma tions thromboses necroses and other local possibly even systemic, affections originating in this manner GEORGE E. BEILRY

Auer J., and Gates, F. L.: The Absorption of Adrenalin After Intratracheal Injection J. Exp. Med. 1916 xxiii 757

In order to subject a living organism to the systematic action of any soluble substance it is obvious that the substance must first reach the circulating fluids of this organism, from the lymph and blood streams the drug may then pass into the tissues and exert its effect. The main routes available for bringing any substance into contact with the tissues are as follows: (1) by introduction into the gastrointestinal canal (3) by subcutaneous intramuscular unitravenous or intraprisal injection (3) by function through the skin, and (4) through the respiratory tract.

luer and Gates purpose in this paper has been to test the possibilities of the respiratory route and they have submitted evidence of an experimental nature which shows that a simple intratracheal in jection of a solution in a normally breathing rabbit penetrates within a few seconds to the alveol chiefly those of the left lower lobe, that absorption is rapid and well maintained and that the procedure may be repeated effectively a number of times even with a substance like adrenatin which decreases absorption. It was also shown that absorption of adren alin from the lung could be obtained at a time when double the dose given intramuscularly exerted no blood-pressure effect whatever and that absorption could still take place after the development of pulmonary ordema, when there was an undoubted dilution of the injection solution with a serum-con taining liquid and when a diminution of the absorptive field had occurred.

The solution injected, after reaching the alveoll is probably largely taken up by the capillaries of the pulmonary veins. This is indicated by the great rapidity with which an instructached lipection of adrenalin may cause a rise of blood pressure. In numerous instances for example the pressure began to use less than five seconds after the completion of an injection equaling and even surpassing in rapid ity of effect intransucular injection. Absorption by the lymphatics probably plays a secondary part an assumption rendered all the more likely when it is considered that lymph nodes are interpolated in the lymphatic pulmonary path, where the bed of the lymphatics probably plays a secondary part.

Injection into the lungs, however offers another advantage due to the vascular arrangement of the absorbing field which could be of value therapeutic Absorption of liquids injected into the lung probably takes place largely through the capillaries of the pulmonary yours to a slight extent possibly through the capillaries of the bronchial veins which empty partly into the pulmonary veins partly into the axygos veins and probably some absorption occurs also through the lymphatics. By far the larger por tion of the absorbed material will thus be rapidly delivered to the left suricle and then to the left ven At each succeeding systole, as long as absorption continues, a fraction of the drug will be driven into the coronary arteries and be able to affect the musculature of the cardiac pump fact the authors state ought to render the proce dure of intratracheal injection a valuable method when it becomes imperative to stimulate a suddenly failing heart as promptly as possible by drugs of the duritalis group

Intratrached injection is perhaps better under the conditions mentioned than the intravenous route for the surface venu cannot always be entered with promptness and certainty even under fairly normal conditions and in eases of cardiac weakness the difficulties will be measurable increased while an intracheal injection can be carried out with ease Moreover the authors state it is legitimate to expect that some absorption will take place from the lung siveoil as long a the heart-lung circulation persists no matter how feebly and that thus some

of the drug will reach the heart to act on this structure itself more promptly perhaps than shen the drug is administered successfully through surface cins. As far as the intramsocular rout is concerned they have shown that the intrarracheal in jection of adreaming fives prompt shough diminished absorption at a time when doubt the dose intramusulative cents. O blood in same effect whetever

The technical difficulties of going an i tratra heal injection in animals re slight. Tra heot m as practiced by the thors it h prese theries fex periments, is not necessary for the inject of my be given into the int ct traches without xposur of the trachea. The hypodermic cedle is inserted through the skin about cm below the larvax i caudad direction the entrance of the needle inter the traches being readily felt. The niection hould of be so rapid that the insected sol tion all the entire tracheal lumen but a should if w down the sides if th traches. If the l m 1 e urely filled an expiration may drive some of the inected fluid t the larynx causing cough. In th. thors xpen ments each injecti of about o 5 cm cons med approximately two seconds

brect dat In the human re a radable the a thora tate as far as thei knowledge goes but a pr ers it would seem that tratra heal niec t on is almost as imple as the lower The free hypoderma needl ould be aserted int the tracheal lumen immediately below the cricoid cartilage Th needl teelf should preferably be connected with the syri ge by short length of rubber tubing to minimize the danger of breaking the needle by a sudden move of the put ent mon t of the sol time should not be too small so that at least a fraction of t ma rea h the alveol as promptly as possible a to a comprobably would suffice

In cooclesi t may be said that the in moration of drugs by intratracheal injection while not as generally applicabl as other methods nevertheless has advantages with h warrant its use also in human therapeutics G own. E. Buttar

Pighint, G. Th. Alterations th. Endocrine of Glands, Especially the Thymus, and of th. Blood Polloving Vegotomy (Le alterations delice ghiardole endocrine, spece del tim. del angue in sergit alla vagot mis. Rev. per di f. cust and let. o 6 til. sto.

In his recenctes on the effects of thymectomy on the Pitplin noticed that in some animals in which the two pneumogastric nerves were accidentally sectioned grave dyspinors and cacheria were produced f llowed after few days by death. The most characteriskie findings at the autopay were amiliar to those found in animals which died in cacheria diet thymectomy I. e. dyspinors, accheria, venous after thymectomy i. e. dyspinors, accheria, venous in the volume of superioral capsule, especially the chromotific parts.

This coincidence led him to undertake further

studies, particularly to find if similar effects might follow a lesion of the vagus whether on not accompamed by a thymectomy. He therefore carried out a series of experiments on fowls and guines pigs sectioning the agus in the vicinity of the neck and study og the clinical yndrome as well as making detailed macro- nd microscopical autoppy tudies. These at dies with the technique described in detail and from them the author deduces the following conclusions.

For la do not survive vagotomy more than four 1 fie days gunear pags about the same time. Among the effect of vagotomy clea distinction must be made between those which depend on the altered bythm of the respiration and circulation with relative our stains of many viscers and a final applytic at 1 md those which are directly impurable to the censuition of the action of the vagus unnervation on certain plandular or yistemic organs. Thus if feet result whigh the abolt tion of the vagus fu cition on the respiration centers and vassels not be second from the suppressed innervation f the agus upon regars which had a direct for feeding correlation with the "agus upon regars which had a direct for feeding correlation with the "agus".

1 Among the organs which react directly to agoin my rice hypophysis the thyroid the chromating land of the capsul which the seen, especially the last named the instead of hyperfunction the thym and apiecen which above atrophic processes, especially the thymus which min is is cause a marked lipoidean degeneration the interernal cortical of the capsul the int ritifal of the ovary, and testicle the meduliary of the long bones which above after at on in lipoid court the circulating blood shows an bornal distribution of whit corpusates, a pre-sleene ef-cutrophiles, od n t ble dimnu

it f coshophiles.

4 The thymns the spleen, the cortical of the capsul the intersitual of the testicle and "ary and the osseous medullary have an excha ge and n internal secretion which is in part regulated by the autonomous action of the vagus.

5 Th vagus being suppressed, the functions of these organs are conseq ently diminished, and the sympatheticum tonus is increased which is manifested by the hyperfunctioning of the chromatifi gland of the capinil (and in a leaser degree of the thymus and hypodysta) and in the increase of adrenain substance in the circulating 100-0. RADIOLOGY

Moriarta, D. C. Radium a Palliative 7 4 m 4 Oast & Gyste Indianapolis 9 0 Sept

Mer a limited experience w th a small amount of rad m in the relief of the symptoms i terminal cancerous conditions of the female breast and pelvis, the uthor report ast cases in which the pain of and hemorrhage had been allevasted. He also m into that other clinical workers in radium have reported the same results without emphasis, however on its usefulness in this particular field. The

author states that he has made no claim to a cure or prolongation of life, simply the alleviation of the symptoms. A symposis of the cases reported shows that pain was releved that the odor was markedly controlled, and that hemorrhage caused. Two died in coma, two months after treatment. Four

are alive and hopeful at the present time. Morlarts believes it possible to produce a toximila with radium locally which may prove serious, and suggests two precautions when using radium locally First, a patient with a low leucocyte count should not be given prolonged applications of radium. Second when radium is used locally it should be accompanied by the liberal administration of alkalies. The author worked with only 25 milligrams of radium element, but for periods varying from 250 milligram hours to 9 600 milligram hours continuously. His convictions are that no case of this type is so desperate and no post-operative conditions to hopeless that radium should not be used with an expectation of the alleviation of the trying symptoms.

Crosby L. G: Deep Roentgen Therapy of Benlan and Inoperable Malignant Conditions by Improved Technique. Colo Med 19 6 xiii, 183

After brief mention of those physical character istics of the roentigen raw which are factors in their use as a therapeutic agent, the author describes the chief differences between the technique employed in present-day deep roentigen therapy and that in use prior to two years ago. To the use of Coolidge tubes, filters, accurate devices for measuring douge and the cross-fire method of treatment he ascribes the very much better results which can now be obtained.

In common with various authors whose reports he cates he has been able to obtain marked improvement or symptomatic cure in a large percentage of deep-scated lesions treated. He concludes that the reentgen ray should be used in all cases of inoperable malignant disease that its post-operative use in malignant cases be universally resorted to that it is a valuable adjunct to other lines of treatment in Graves disease, splenic leukemia, and Hodgkin's disease and that in menorrhagia and myomata it be employed in any case in which operation seems ill advised.

Anoun Hartrovo

Hirsch I S: Roentgenographic Control of the Pneumothorax Treatment of Pulmonary Tu berculosis. Med Rev. 1916 lixxix 1029.

The application of the roentgen method assists in the selection of cases, permits the estimation of the degree of collapse and of the effect on the opposite of lung indicates graphically the displacement of the heart and mediastinum and sids the early discovery of complications.

It appears almost impossible by physical examination to determine the extent of the pneumothorax the position of the collapsed lung or to estimate the displacement of mediastinal structures. These dif-

ficulties demand all the diagnostic means at our

Both methods roentgenoscopic and roentgenographic, should be employed. With either ontitled the examination is incomplete. No description of the fleeting image seen on the fluorescent acreen how ever accurate, can compare as a graphic record with the permanent plate which also gives the finer structural detail not to be seen with the screen

Roentgen atudy is made at three periods (1) preliminary for the estimation of the amount of discase (2) during and immediately after the injection and (3) later to determine the amount of the collarse restitution etc.

There appears to exist a belief that opening of the pleura and the admission of air invariably results in immediate and complete collapse of the lung, but it has been demonstrated that the lungs may functionate while there is a large pleural opening and that considerable quantities of gas are necessary to obtain extensive collapse.

Examination after injection gives the following data

r The degree of pneumothorax Is the air present in all parts of the pleural cavity or confined to a particular part?

2 The complete or partial collapse of the lung and its mobility

3 Presence or absence of plcural effusion.
4 Degree and manner of mediastinal displacement. Is there excessive strain on the blood vessels?

(The heart displacement is not proportional to the amount of gas injected and varies with the same amount of gas.)

5 The movement and displacement of the dia phragm.

6 Subcutaneous emphysema presence and de

7 Restitution and reinflation.

8 The effect may be studied from time to time and comparsions made. Dayin R. Bowen

Clark, W. L.: The Treatment of Nævus Flammens and Allied Conditions by Filtered Ultraviolet Rsys. Employing the Compression Method of Application Therap Gas 1916 xl 312

Ultraviolet rays, as applied by the author were found most efficacious in the treatment of port wine nævus, lupus crythematosus cezemu rubrum and acne rosacca. He used a kromayer modifica tion of the Cooper Hewitt mercury vapor lamp for generating the rays which were passed through quartz lenses cooled by a continuous circulation of water. He found the interposition of a thin disk of blue colored quartz of decided advantage, this act ing as a filter for the irritating wave lengths and in creasing the penetration.

The tissues treated were firmly compressed to produce a temporary ischemia and the surrounding structures were protected by the use of zinc-oxide adhesive plaster which effectively cut off the rays. An application of 30 to 40 minutes was found to produce the maximum of beneficial results. This was re peated, if necessary after three weeks and some cases required a third or fourth application after a similar interval.

A few bons after treatment a reaction set in. First the aren treated became alightly darker and moderately swollen and ordenat us. This reaction became more intense for about 48 hours and then began to subaide. Slight desquamation of the skin occurred and after one it two weeks hours and became markedly lighter in colo Similar results became markedly lighter in colo Similar results followed each treatment althought a leaser degree. Brunettes were fou diess susceptible than blonder. Children reacted more favorably than adults. The best results were obtained with those navi which fielded readily opon pressure. Where connective tissue hypertrophy was present absolute obiliters iton rarely occurred but marked improvement re

The cases of port vine news thus treated are cited in detail with results varying from slight improvement to complete success. Partial failure in two cases was sarribed to a coating of carbon on the quarts lenses, and a word of caution is given t avoid this. In some of the cases having stars due t previous treatment marked improvement of the scar followed the ultraviolet light treatment. Enlargement of feat res due to blood engoyeement complicating some of the cases was materially re-

The author concluded that filtered ultraviolet rays applied by the compression method produces good cosmetic results in the treatment of port wine new't telangiectasis, reacca, and other superficial "ascular skin lesions. A Hasrow

Burns, J. E. Thorlum, A New Agent for Pyelog raphy Bull. John II phins Hesp 9 6 zzvil, 57

Ever stace the introduction of pyelography by Voelker and von Lichtenberg in ood to prime hopotrance in the role of remail diagnosis has readily been recognized. Although various tempts have been made to replace collarged the medium recommended by them for injection, t has provent be the pyelographic agent par excellence up to the present time. The various colleidal solutions of sails of heavy metall, which have been tried as substit tes, are those of allver iron bimenth, topper lead and metally not only the properties of the sails of bimenth call clum, and magnetium. All of these solutions form sciliment at ding and while being for the most part quit opaque to the reculer may are viscon morrover. great many are quite toxic and first at

The chief object in to collarged is its irritant action when it escapes into the tissues, and as a matter of fact, there have been a number of deaths reported following its use. Its elimination from the intany tract is somewhat prologoid on account of its viscosity. The fact that it stains everything with which it comes in contact makes it objectionable. It is also quite expensive for this reason its use for cystograms and large hydronephroses is often prohibitive.

Since the opacity of a substance to the roentgen wy depends upon its atomic weight thorium, being next to the heaviest known element, was quite idealing next to the heaviest known element, was quite idealing tigation. The nitrate and chloride of thorium are quite readily soluble in water giving a clear, mark edily add and astringent solution. These solutions, however are quite irritating and it was necessary for the authors t discover some means of combining the substance to render a less irritating product.

After a careful series of chemical studies of the various combinations into which thorium may enter, so toon containing a double citrate of sodium and thorium, together with an excess of sodium citrate and some sodium nitrate, was found to possess the qualities desired as being necessary for an ideal prefographic medium. After a careful clinical and ex-

perimental study the authors conclude as follows. Thonum solution fulfills all the conditions necessary for an deal pyclographic medium. Clinically there has never been the slightest evidence of tox icity in a series of one hundred and twenty-five cases, the amounts used in single case varying from a few cubic centimeters to almost a liter. This alone is proof of its non toxicity.

Experimentally although in a few instances death has followed the injection of large doses into the peritoneal cavity and tissues of animals, larger doses intraperitoneally and intravenously have produced no ill effects. That the solution is non-irritiating is above by the bience of urinary symptoms after its use, and the absolute lack of any such evidence crustococceally and at operation.

The pyclograms and cyatograms made with this solution show a sphendid shadow which possesses an unusual clearness of deliceation. The solution is clear and wattery therefore it possesses a great degree of fluidity permitting its ready climination from the urlanty tract. It is perfectly clean and does not stain the linea. In this particular it possess another marked streaming over other solutions of the property

MILITARY SURGERY

Metcalf J and Keys-Wells, E. N Th Anatomical Position of Localized Foreign Bodies. Lanert Lood. 9 6 ctc, 078.

The localization of foreign bodies has been greatly simplified with the improved methods. Many cases arise, however where it is important to know what structures lie bore or below a foreign body For example, in the thick perts of the body it may not be possible t accurs satisfactory pictures in two planes. It is therefore necessary to estimate the depth of the foreign body in centimeters and this can untuilly be done. The question as to the relations of the foreign body are not greatly simplified, how ever unless the depths at which anatomical struc tures lie are known by the surgeon. For example the radiographer reports a bullet to be o centi meters deep from a mark on the front of the thigh over the great trochanter If the surgeon knows that the average depth from the skin to the great trochanter anteriorly is 10 8 centimeters and from the back o centimeters he would be justified in concluding that the foreign body lay just in front of the trochanter

The author has tabulated a careful list of different parts of the body with the corresponding depths at which the different structures are placed beneath the surface. I H. SKILES

Dehelly and Dumas: Sterilization of War Wounds (Stérilization des blessures de guerre) Presse med 1916 p. 103.

The authors give the technique of their treatment for the rapid disinfection of war wounds. They use a solution of 1 200 of hypochlorite of sodium prepared according to Dakins method. The special technique for obtaining access to the deeper parts of wounds is described. The treatment comprises surgical intervention, continuous instillation, and careful after treatment Intervention is done aseptically as under operative conditions and following this it is necessary that all parts of the wound be kept in permanent contact with the antiseptic solution. For closure of the wound the authors prefer adhesive strips to sutures.

Of 155 cases of extensive wounds due to shells. bombs, and mines which have been treated by this method 135 or 87.4 per cent have closed. Of these 110 were cicatrized in less than 30 days. Twenty five of the 155 cases were complicated with fractures and of these 18 were cicatrized in less than 30 days. W A. Brennan

Flessinger Molroud Nimier and Vignes Study of Pus in War Surgery by the Pyoculture Method of Delbet (Etude sur le pus en chirurgie de guerre par la méthode de la pyoculture du Delbet) Presse med 1016 p 107

The authors have studied the method of pyoculture in a surgical field ambulance and their experience is based on 120 practical tests in different types of war wounds. They have endeavored to ascertain whether pyoculture could determine the kind of operative intervention.

They find that a positive pyoculture does not suffice to indicate intervention thus in 58 per cent of their cases a positive pyoculture was followed by a normal evolution of the wound without interven tion. The necessity for intervention is only marked in 33 per cent of the cases. On the other hand when the pyoculture is nil or negative, it does not always indicate that intervention will not be necessary Thus in 13 per cent of the cases, where the pyocul ture was nil or negative intervention was necessary In the presence of a pyoculture which is nil or nega

tive expectant treatment may be advised it may be necessary to resort to operation.

W A. BRENMAN

Proust R. Considerations on Some War Injuries After Eighteen Months of Campaign (Con alderations sur quelques plates de guerre après dix huit mois de campagne) Bull. et mêm Soc. de chir de Par 1016 xlil, 1270.

Proust submits some general ideas gained from eighteen months experience in field ambulances. From May 1915 to February 1916 while in charge of Surgical Automobile Ambulance No 1 Proust cared for 1 800 wounded, most of which had severe, infected wounds The mortality was 23 per cent.

In injuries to veins or arteries the author ligates the vessel some distance above and below the injury and resects the injured part

In bone lesions free splinters of bone should be removed but care must be used as regards other lesions

For articular wounds, Proust believes that when any articulation is traversed by a projectile other than a bullet the opening must be largely widened so as to ensure drainage and certain resections such as of the patella and astragalus may have to be resorted to Patellectomy has given 15 recoveries in 19 grave wounds of the knee 16 shoulder resec tions gave 14 recoveries. Operatory indications are exceptional for nerve-resections.

In the case of wounds which are difficult of dis infection even after free opening up Carrel a method i.e intermittent instillation of freshly prepared Dakin a solution has given the best results.

When amputations are necessary Proust always resorts to plane section. In the 1,800 wounded treated there were 152 amoutations with a global mortality of 15 per cent distributed as follows

thigh mpatetions per cent mortality per cent mortality g leg amputations g loot amputations to arm amputations a lorsers amputations per cent mortality per cent mortality g gow cent mortality

The mortality however has decreased under better conditions, etc. Thus from June to July the mortality was 72 per cent from September to Novem ber 32 per cent from December to January 20 per V. A. BREXINAN

Freund II: Experiences with Gaseous Gangrene in War Surgery (Kriegschlrurgische Erfahrungen bei Gasgangraen) Beitr z. Eliz. Chie., 1916 zevill,

Freund gives his experience with gas gangrene based on the treatment of 39 cases 10 of which were of the epifascial type and 29 deep muscular tissue gangrene

The history of gas gangrene is traced since Velpean first made observations on the condition in 1855 and since the discovery of the gas bacillus by Fraenkel in 1882 The epilascial form of gas gan grene gives its indications between the skin and the fascis. The typical discoloratio of the skin, the intense ocienae, the changes in the subscutaneous tisrues, and the finding of the gas bacillus are characteristic. This epithelial form is sharply differentiated from the subscalal muscula form and may be considered a distinct battly. The specific symptoms appear on the third or fourth

day

The subfascial form of gas gangrene is distinguished by the unusually violent halting pains in the wound remarkably accelerated pulse and great unrest of the patient. The clinical picture is not considered to by the seventy of the injury nor by any local symptoms but the vignifiy of the injury.

is exceedingly sensitive.

Fruend describes the three different tages of alteration which may be observed in the muscles due to gas gangrene. In every case it is observed that the peripheral part of the injured muscle is

more involved than the proximal part.

It he lighter forms, incisions in the fascia, widen ing of the wound, and ovygen insuffizion raffice to effect recovery but in the sublascial forms even deep and wild multiple incisions will often not suffice and in 8 cases so treated by the uthor he was obliged to amputate the limb in 6 with deaths. Kuemmell a statistics of mortality was 3 per cent and Frans 2 sper cent in sublascial cases.

In the treatment of the subfascial form early diagnosis is important. Free opening up of the parts and excision of the diseased parts of the muscle is the best procedure. Sometimes it may be necessary to remove a whole group of muscles.

Amputation must be resorted to when in spite of a ch energetic action the necrotic conditions are seen to spread in the muscles or the muscles of the proximal joint are involved. W. A. BERDOLAF

Policard, A. and Desplas, B. Rescarches on th Secondary Suture of War Wounds (Rechérches sur la suture sécondaire des plaies d' genre) L'em chir 9 6 dll. 43

This article which is the result if the collaboration of bl logist and surgeon is said to be nly a preliminary study. The thore give the details of four observations, describe their techniq e, and discuss the physiology of sounds with regard to secondary suture. They think that there is an essential of ference between secondary reunion in wounds and reunion by first intention in the case of contrative wounds.

In the latter the phenomena are exclusively those of conjuncti e regenerati n. But w wounds are always infected, even if only slightly so and to the thesi reparation must be dided the defense against infection. The coexistence of a inflammatory reaction with co junctly reparation gives special phase t such injuries.

Study of such war wound between two points of suture shows that there is multiplication of germs while scurcely one may be found in the evudate before suture after it no, so or even 80 germs may be found, including streptococci bacillus pyocyaneus, etc. This multiplication begins immediately after suture and lasts three to five days From the fourth to the seventh day germs are no longer found

At the same time there coexists a notable leucocytary reaction. There is an afflux of neutrophile polyunciens. When the inflammatory reaction is subsiding masses of leucocytes undergoing n clear transformation are always new twith and the presence of such when noted is always an excellent index of the satisfactory evol then of a sutured wound.

It is important t follow the evolution of a second arily utured wound by frequent interoscopical examination of the serosity which flows between the two points of surface. The mode of a chosecond ary a ture is little know but it represents such a surgical and social advance that multiple researches by discovering and comparing the factors which constitute it will lead to its generalization. W. A. Berrour

Perret, M. Results Obtained from Employing Carrels M thod in War Surgary (Resultats obtains per l'emploi de la méthode Carrel et chirurgie de guerre). Ball Acad 4s mil Par 9 0 lury 444.

From August to December 10 5, Perret treated Its severely wounded cases in his ambulance sevice by th Carrel method. Of the series 78 were lesions of the soft parts 33 were ossoon lesions. There were no deaths. All the wounded have recovered and are in good condition. Not a single amputation was necessary. The method has eliminated infection according to the author.

The a thor states that all surprors at the fro t are unanimous in declaring that the wonder treated by the Carrel method rapidly recover. At a whether Dakins flidd is the only one capable of bringing about this result on on there is no longer any doubt and any delay in applying he considers grave fault. W. A. Bannara

Uffoltx Secondary Union of War Wounds by First Intention in the Fleid Hospitals (La Réumon sécondaire des places de guerre par premier intention dans les formations muitaires d 1 vant) Ball, Aced de mél. Par o 6 1 try 31c.

The results busined by Carrel and his conferent in the secondary returnon of non-suttered wounds were obtained under very favorable surgoal conditions in a rear hospital but it was questio ed whether these estilts would have been obtained in a field zervic hospital where such favorable conditions did not seen to the secondary of the conditions of the secondary of the secondary of the secondary of the secondary of the secondary report of Wilbits demonstrates that Carrel actortive method of infection, if it may be so termed, is pplicable at the front as well as at the results.

Of 8 wounds in which the method was followed with success, 12 were abell or grenade wounds, which are generally infected, and 6 were caused by rifle bullets but of such a nature that they might be classed as infected wounds. The rule has been followed in these cases of not suturing contused or infected wounds and allowing them to unite by secondary intention

In his communication of October last Carrel discouraged auturing He preferred the employment of aggintinative strips to draw together the exter nal as well as the deep edges of the wound In large and deep wounds the strips are applied after having the deep edges approximated by some strength ening stitches. This procedure favors cicatrization. from depth to surface. In the 18 cases now reported to were sutured but the suturing was late and after the freshening of the edges in 6 cases adhesive strips alone were used and in 1 case of a large and deep wound shell of the arm reunion was effected by deep sutures on the ninth day. This was followed by the use of adhesive strips and cicatrisation was complete by the forty-eighth day Under the usual treatment the repair of such a wound would take from three to four months. The author believes that the Carrel method has abridged the treatment of war wounds by one half or two-thirds

The technique followed in these cases is that of Carrel, but Poxai is not quite sure that the modified form of Dakin's solution has been used Carrel has intimated that he now uses Dakin's solution

prepared as follows

For so liters Chiloride of chalk 200 grams Carbonate of soda dry 100 grams. Blearbonate of soda 80 grams. The ingredients are mused cold with 5 liters of

ordinary water triturated, etc. No heat is em ployed. W. A. BRENHAN

Enderien Experiences of a Consulting Surgeon (Erlahrungen eines beratenden Chirurgen) Beitr 2 klm Chir 1916 cvill, 419

Enderlen gives his expensences of German was surgery from his diary notes. In the early part of the war the conservative treatment of wounds was found to be unsuccessful and after October 1914, active treatment was instituted in lieu of it.

Gas phlegmons, or gas burns as they are called by Fraenkel were seen not only in the superficial but in the deeper tissues and seemed to result from all kinds of wounds. In the lighter epifascial phleg moss incisions and bandages soaked with H₂O₆, or actic acid and oxygen insufficial but in the more serrous cases and deep involvement amputations of limbs was necessary.

During 1914 Enderlen lost 27 out of 34 cases of tetanua, although all the usual means were used The scarcity of tetanus at the present time is due to

prophylactic vaccination

Cranal wounds since October 1914 have been re-examined and active measures instituted Drain age and suturing have given good results. In the case of chest wounds the thorax was closed when possible In larger defects of the chest wall the

lungs were sutured in to prevent mediastinum depression. Autopsy in two cases showed completely collapsed lungs and empyems. Hence it is best before closing the chest cavity to inflate the

lung by simple pressure

Enderlen operated from the beginning in intestinal gunahot wounds and had 67 successful cases out of 154. After ten hours if not operated the chances of success are alight. Liver and kidney injuries are better adapted for conservative treatment. Intraperitoneal bladder injuries are mostly fattal. Extraperitoneal bladder injuries can usually be managed with continuous catheterization. Urethrotomy is generally called for in uretheral injuries.

In spinal region injuries the outlook is not entirely hopeless. Treatment should be instituted even though the prognosis is gloomy. In the lumbar spine the results give even better promise. Ender lein mentions a few cases of sectioned nerves which

were sutured with good anatomic result

For vascular injuries Enderien has used ligatures, suturing and transplantation. The ligature is generally confined to the smaller vessels but suture will be used in the femoralis popilited carotide and other large vessels as in these cases the ligature of the vessel is liable to cause gangrene in the limb. In the brachial and femoralis Enderien both su tured and transplanted with good results.

W A. Brienman

Ftolle, J and P: The Advanced Surgical Post (Le poste chirurgical avancé) Res do chir 1916 xxxv 302

The authors believe the establishment of ad vanced surgical posts in the battle line is necessary. In such a post properly constructed and protected the surgeon can operate safely and calmidy. Such operations are not only acceptable, but are demand ed by the wounded. The utility of such posts as regards hemorrhagic utilities is unquestionable.

In other condutions such as abdominal wounds early intervention is the essential condition for success. For such the advanced post is necessary Amputations must yield to early resections. Infection is next to harmorrhage the cause of numerous amputations which can be avoided by care and attention in the advanced post. Where wounded cannot be despatched every day to clearing hos pittals the advanced surgical post is indispensable.

Details are given of 84 operations carried out in such a post also of the necessary accommodations construction and equipment WA BREDIAM

Clark, S. M. D. Discussion if Cancer of the Cervix.

Uterl with Especial Reference to th. Combination Method of Treatment. T. St. J. Med.

9 6, xii, 3

For convenience of discussion, cervical carcinomata
are divided into four groups as follows

I I the first group are found the incipient cases. The ubcertain is suricily limited to the cervix and there is a evidence of lateral infiltration. The uterus is freely movable. Menarciation is alightly prologed with an occasional irregular show. There is an irritating vanual discharge. The patient is constitutionally impaired and a good surgical risk. Cases falling in this group are irrited to the best and the redical removal. The Werthelm removal is undertaken.

In fat women, the Percy cautery alone gives these early cases their best chance of cure since the technical difficulty of carrying out the radical plan at one rest and further the high primary m rtality.

would discount its feasibility

It is most deplorable that more cases do not fall under this first group. Once there is thorough co-operation of an alert profession with an ed cated public the percent ge of early cases will increase.

In the second group the cervix is well infinited with cardnoms, with a light netresion to the vaginal wall. Though as yet there is no pain in the sides, still a definite thickening and alight involvement of the parametriam can be palpaied. The uterus is still movable with irregular flowing and at times, profuse loss of blood. There is secondary anemia and the patient is consist it naily below par. Many of these cases succumb from the operation since they are poor successive from the operation structure of the patient is consistent in the patient is the party cases succumb from the operation structure of the patient is consistent of the patient in the party cases as successful to the major operation. It is bere that the Precy cauttry in combination with ligation of both the internal line and oversian stretes, as two-size senting, so excellently serves the desired code.

After the preliminary sitting, these patients are then to bed for ten days when they are allowed to be up and are placed on forced feeding and Blaud plats. I from three to five weeks there will be noted a marked change both locally and constitutionally. With the cessation of the hemorrhage as well as the tozemias, the hemogl bin will have risen from 5 to 30 per cent the vessels are full, the entire economy has improved and from having been adoubtful surgical risk, the case is own frankly operable state. Radiotherapy is in its swadding others it is ow in its experimental stage and it is

too early to come to conclusions. The only attitude

3. In the third group the cervis is markedly inditated with cardinoms having extended at least an nch n th vaginal wall. U unlly there is a large crater rhigh exculfower masked impairment of mobility with noted lateral inhitration from the low regment of the uters. Pain no or roboth sides is experil. Procounced cachedia and anamus are present. C nut it tionally and locally they are inoperable. Hierotore these cases have treated from the uterity hopeless standpoint.

The combinati method of treatment can be adopted t ad antage in this group. While in the abdome for ligateo a thorough prospectus of the xtension of the disease can be gained and the lymphatics removed as guide to the possibility of f t re surgical procedure. It is in this stage of the discuse that we are pt in the repeated use of the cautery t ing re the bladder or possibly the rectum. In some of these cases the local and constitutional condition will have so decidedly improved fter the cautery and ligation that fudging from the mobility of the ut rus, it will be thought possible to do a complet operation for after the upper two-thirds of the terms is freed and the ureters detached from the focus e usually finds that the upper two-thirds of the terms part from the lewer infiltrated segment The fourth group comprises the absolutely hopeless class of cases. The rectum, bladder and vagina are in one conglomerate, infiltrated mass there is frequent and at times, copious flowing with

popeless class of cases. The rectum, bladder and vagina are in one conglomerate, inflirated mass there is frequent to distinguishment of the properties of the state of the st

Tennant C. E. The Use of Heat in th Control of Inoperable Cancer Cel Med 9 6, xill 76

Modern investigati as seem to prove conclusively that heat is one of the most effective therapeutic means we have in the control of cancer provided it is properly applied. The subsequent use of the N-ray with cross-fire polications of the rays from hard tube is, no doubt, good after-treatm t. The source of the heat may be varied from hot long-to thused and fiver from installation, in order to spread evenly a temperature of 100 to 150° F throughout the mass,

In applying the treatment to cardinoms of the pelvis or other easily accessible structures the Percy cautery irons are probably most satisfactory. The use of heat with the Percy irons, as a method of treatment is proving very satisfactory in inoperable cancers of the lip face neck, and breast. This should be followed later by radical excision thereby doing away with the possibility of metastatic recurrence.

The experiments which the author has made on large masses of beef lead him to believe that in the d'Arsonval current we also have a very potent and serviceable means of obtaining the same or even better results in tumor masses located in some of the more unaccessible portions of the body. This conclusion is based upon the fact that in every test made the d'Arsonval current raised the average temperature of a given mass 24. Fingher than the cautery frons did in just one half the time consumed by the latter.

Chiaje, S delie: Red Myoma of the Uterus (Mioma rosso del utero) Ann di ostet e ginac. 1916 xxxvili

The so-called red myoma of the uterus was first described in 1905 by Polloson and Violet who re ported a few cases. The tumor is so-called on ac count of the characteristic red color like raw flesh in appearance which it presents in section. Since 1905 a few other cases have been described.

The author gives a summary of all cases found in the literature and describes a case of his own. In discussing these tumors the author considers that from the anatomopathologic standpoint they are usually atuated on the anterior wall of the uterus and are constantly interstitual. They are almost always homogeneous and when exceptionally distinct nodules occur they never have the same structure but are fibrous in character The tumors are covered with a fibrous capsule and in section show the characteristic coloring The anatomopathologic features which confer a certain special physiognomy on these tumors are (1) intense vascular hyperplas-12, (2) interstitial harmorrhagic focu more or less diffuse (3) embryonic character of the muscular elements. Clinically the tumors are observed to increase rapidly and give rise to pain and fever

The brusque manifestations the manner in which they occur and the periodicity which they assume, give a certain clinical picture which has a diagnostic value. In the interpretation of these phenomena congestion is an element of the greatest importance. The morbid conditions with which red tumor of the uterus may be confounded are benign or sarcomatous fibromata in course of degeneration. A careful examination of the character of the phenomena will permit of a differential diagnosis but it is more difficult to distinguish the tumor from an ovarian cyst with torsion of its pedicle.

In the case reported by Chiaje the patient showed the local and general clinical features of a peivic tumor and the case was diagnosed as an ovarian cyst with twisted pedicle. This diagnosis however was altered on opening the abdomen when it was seen that the tumor was developed on the anterior uterine wall and a hysterectomy was done. Examination of the tumor showed the anatomic characteristics of a red myoma.

Deluca F A A Case of Unilateral Polyptiorm
(Edermatous Elongation of the Uterine Cervix
(A proposite de un caso de dongacion cedematosa
cervical polipoforme unilateral) Rev de la Asse
méd Argent. 1916 xxiv 611

A case of this very rare complication of labor is reported by the author in a woman of 28 a H para, who twelve hours after the onset of labor showed a fleshy tumor in the vulva, the size of a hens egg which though reduced reappeared as the pains be came frequent and intense. The woman was removed to the hospital. The tumor was then the size of an orange soft and pasty wine red in color and attasted on the antenor cervical labium. One hour later the labor terminated spontaneously After the birth the tumor gradually diminished in size and disappeared about two months later.

The author's research shows that this complication originates usually during labor and that its situation is by choice on the anterior labum. Several factors contribute to its causation. It is characterized by a distention and prolapse of the anterior wall of the inferior segment elongation of the supravaginal portion of the uterine neck and edematous tumoration of its intravaginal part the dilatation of the neck being at the expense of the posterior cervical labum.

Deluca thinks that the condition should more correctly be termed cervicosegmentarial or isth micocervical unilabial polypiformædematous elongation (of Rouvier)

It always occurs with a cephalic presentation and nearly always in multiparts. Spontaneous birth is always possible. The causes may be predisposing or determining. In the first group are comprised the anatomic constitution of the inferior segment multiparity narrow pelvis prolapse and utcine anteversion, exaggerated softening of the inferior segment posterior presentation etc. in the second group energetic utcrine contractions carry presentation, and premature expulsive force

HAR TO B MATTERS

Fitzelbbon, G. Th. Etiology f Lterine Prolange and Cratocele. Sure G ar & Obil a b

The author considers that some operat h uld he devised as the all around basis for the urer altreatment of these conditions. All enders points to the fact that prolange of the uteru 1 7 total are the result of some damage d ing pa turition. The prob bility is that it the same structure which is damaged in pearl all th In nulliparous women the defect is p obabi th

same, but here the fault is congenital Lacerations of the peritoneum no matt extensive hare no effect upon the elevation if the nterns, and such lacerations could not possibly involve that part of the levator and muscle which supports the cervix uterl. The structure which is considered the main support of the pelvic organs is the visceral or endonelyic layer of pelvic tascia. This is very fully described and shown t form complete pelvic disphragm broken by the passage through of the viscers and parts attached to them. This together with the levator ani muscles forms the pelvic diaphragm, the fascia taking up the constant arrain and the muscl acture by re-enforcing the

fascia against pressure. In descriptions of the fascia the upper or true supporting part of the fascia is quite neglected and the thin part which follows the levator am muscles as their inner sheaths is shown as if it were the whole of the rectovarinal fascia whereas it is The vacina is shown by diagrams t portant part bliquely below the fascis, the fornices only slightly go above the plane of the fascia while the uterus is chiefly above having its greatest attach ments in front of the plane of the broad ligaments. The bladder is wholly above the fascia which separates it from the anterior vaginal wall. Prolapse of the uterus is the result of runture f the fascial sling cross the pel as attached to the sides of the cervix and the lateral vagunal fornices. When this is damaged prolapse of the uterus bore takes , the vaginal fornices being gradually inverted but the bladder being retained well up. When the fascia in front of the cervi and the anterso vaginal wall is ruptured cystocel develops, but the cervix is fully maintained. These two conditions may be combined and the whol pelvic co tents comes down.

The failure of the present-day operations is the result of efforts t cure prolapse of the merus by an operation only suitable for the cure of cystocele and the failure to recognize that interposition is useless unless the cervix is maintained well up. This is effected in a certain number of cases by the practice

f doing a high amoutation of the cervix and cover i g over the tump with the vasdnal wall, in doing so a certain amount of fascia is caught in and those ases in which a sufficient amount of fascia is caught early in cares while the others, elabore but the need

f cat hing in the fascia is not recognized. The iscera can be fully supported by an operation t unite the broken fascia in front of the cervix and hel a the bladder and this can be done without remo al of organs r such distortion as will render hildbearing in any way hazardous and can theref e be adopted in the young parous woman with-

Pascal, A.: Treatment of Uterine Prolapse (Traitement d prolanem terin) Presse #44 0 6 p t t

For simple retroversion where there is no adnexal lesion Pascal believes that Alexander's operation under local angesthesus will suffice. If adnexal inflammation is suspected a laparotomy abould be done and the procedure of Doleris followed, which consists in fixation of the two round ligaments in a buttonhole made in the two large right muscles. If the ligaments are weak an abdominal hysteropery may be necessitated.

For prolapse with predominance of cystocele in women of 40 Pascal recommends vesicovaginal interposition limited to women between to and

45 years For prolapse with atrophied uterus, flaccid aginal walls, and gaping vulva the author is of the opinion that the Kocher operation does not give sufficient guarantee to assure the fusion of the uterus with the anterior bdominal wall and be therefore uses th Murphy operation, following the Mayo tech-

In the case of women with atrophied uterus and relaxed walls gaping vul a, and permanent cystocele the uthor uses varinal hysterectomy completed by median sut re of the two large ligaments and permeal reconstitution. In old hysterectomized subjects where the bramental stump was not sutured to the uterine or vaginal stump it is necessary t excise the vagina, or in case of a younger patient to make laparotoms and by the varinal or cervical stump to the abdominal wall.

Whenever an operation f r prolapse has been carried out the surgeon must remember that th muscular tass es are insufficient semi-atrophied, and that such operations leave behind a three of frazile cleatrices. If the technique is good, surgical recovery is the rule but it is highly necessary t strengthen the recovery by a regeneration of the muscles. This can be effected by general hypicue and Brandt gymnastics which restore tonus to the atrophied muscles. II A. BREXX AX.

McCann, F. J. Th. Treatment of Backward Dis placements of the Uterus. Med Press & Circ., 0 6 cl. 410.

McCann has written a very lengthy paper upon the old but very important subject of backward displacement of the uterus and the methods gen erally employed for its correction.

Treatment as the author states, has very mark edy improved in recent years owing largely to the advances made in gynecological surgery and to a better understanding of the causation and sequelse of the condition.

The subject is outlined as follows

- r Congenital uterine displacement
- 2 Retrodisplacement due to excessive mobility
- 3 Traumatic uterine backward displacement 4. Treatment of backward displacement in virgins.
- 5 Treatment of backward displacement in multiparæ (a) method of replacing the uterus, (b) treatment by pessary, (c) treatment of backward displacement when pain and tenderness exist (d) treatment of fixed backward displacement
- 6 Treatment of backward displacement in parous women (a) when the uterus is replaceable
- (b) when it is fixed.
- 7 Operations for the correction of backward displacement (a) abdominal (b) vaginal.
- 8 Backward displacement after the menopause.

 a Backward displacement in association with
- uterine and ovarian tumors.
- 10 Backward displacement of the gravid uterus. Treatment may consist in (1) spontaneous replacement (2) bimanual replacement (3) operative replacement.

The author has given under each of these headings a general plan of procedure calling particular at tention to those methods most successful in his hands. Some of his methods are original the majority however are those of other gynecologic surgeous modified or not laway I Marringwa.

Taylor J C. Vaginal Hysterectomy \ 1 1/ J 1916 cl 53

After a brief historical sketch regarding vagunal hysterectomy, the author elaborates upon the present-day indications for the operation and describes his method of performing it

The indications for vaginal hysterectomy as given by the author may be tabulated as follows

- r. All cases in which conservation of the uterus is not to be considered except where tunefaction renders the uterus too large to be delivered per vagina or where extensive adhesions render impossible the proper approach to the uterus.
- 2 In intraligamentous and retroperitoneal growths
- 3 In women past the menopause who for any reason require hysterectomy except in those cases where the size of the uterus prohibits its delivery through the vagina.
- 4 In complete prolapse of the uterus after the menopause
- 5 In cancer of the cervix where the disease is too far advanced for a Wertheim operation yet it is deemed advisable to remove the uterus for the rellef of pain and foul discharges Such cases

may however be radiumized and later a Werthelm operation performed.

- 6 In cancer of the fundus where the growth is still localized.
- 7 In epithelioma of the cervix occurring in old women who have serious heart or kidney trouble. The vaginal route should never be chosen where

The vaginal route should never be chosen where there is any involvement of the appendix or in testines which might need attention or in complete prolapse occurring in young women.

The author's method of performing vaginal hysterectomy consists in the usual anterior and posterior separation from below upward after which the uterus is bisected the adnexa inspected addictions if present are freed, and then each half of the uterus is removed by clamping from above downward. The space between the clamps is properly packed with lodoform gauze and a self retaining catheter is left in the bladder. The clamps are removed in torty-eight hours. The gauze packing is removed on the sixth or seventh day and lighter packing replaced until healing is completed.

This technique is modified in the presence of fibroids or complete prolapse. Where fibroids in crease the size of the tumor very materially V-shaped pieces may be continuously cut away until the top of the fundus is reached when division of the remaining tumor may be accomplished. In case of complete prolapse the ownans and uterine vessels are ligated the clamps removed and the base of each broad legament is sutured into the vault of the vaging which is sufficient to hold the vaginal vault high and keep the bladder in normal position.

In conclusion the author states that in a series of over 300 vaginal hysterectomies there has not been a single death traceable to the operation itself and therefore he highly recommends this operation in all autable cases Harvy B MATRIES.

Truesdale P E.: Vaginal Hysterectomy for Procidentia with a Report of Fifty Cases. Boston M & S J 1916 clary 13

The author employing a special technique has performed so vaginal hysterectomies for the cure of prolapsis uter! The procedure as recommended is limited to the class of cases in which conservation of the uterus may be disregarded. The author's cases averaged to years of age.

The technique employed differs from the usual vagunal hysterectomy in that the author instead of making the incision through the broad ligaments in the usual manner extends the line of incision in ward far enough to include a considerable portion of uterine muscle. By bringing together the broad ligaments with their appended portion of uterine muscle there is formed a central body for the resistance of intra abdominal pressure and firm support for the bladder

This method, as the author says, is the same as the Watkins-Wertheim procedure, except that the greater part of the uterus and all the cervix are removed before the interposing act is accomplished.

I high permeorraphs completes the operation. There is a tabulated end result eport of the so caces operated upon by the a thor which shows that 4 per ent were cared 12 per ent were narrially cured and o per c at were failures

When the taming g finger reveals complications (the ions, t be overan die se etc.) the fell ing proced re a adopted. The abdomen is opened in the midl by the leterion method or by tra +

recinci on the low rend of the strain oblique in son re joined and the abdomen opened the I'l neastiel procedure. The visting conditions are tre ted, and the openi g closed coordi g to the Pfannenstiel method. Other steps are foll ed out as above. In pyosalman, tubo-o arian abovess, adextensive adhesions this procedure is of great value and is more applicable than the bi-inguinal incusion.

The advantages of the method are case of ex posure of round bgaments rapidity of operation single incision later hidden for most part by the puble hair the pull is in a forward rather than a lateral direction and permits of the application of a Pfannenstiel or Peterson procedure

Claims for originality are (1) All other operators employing the transverse suprapuble incision do so with a predetermined intention of opening the abdomen either in the midline or by the Pfannenstiel method which the author only exceptionally resorts to (2) simple fixation of round ligaments in the midline to the abdominal fascia instead of to I oupart a ligament or the inguinal fascial wound and certain features in connection with the technique.

Stanton, E. M: End Results in Cases Operated for Salpingitis. Am J Obst. N Y o 6 buili

The author bases his report on a careful study of the end results of 100 cases he has operated upon for pelvic pentonitis of tubal origin, and a study of the literature on this subject Among 93 patients not subjected to hysterectomy there were several who for a time complained of leucorrhoea but grad ually the uterine infection subsided and today he thinks each of these women is better off with her organs intact than she would otherwise have been. His experience confirmed by carefully checking the late results following operation has led him to be lieve that the operator should remove as little as possible and trust much to nature. C H. Davis

MISCRILANEOUS

The Causes and Treatment of Sterillty in Women Therap Gaz., 19 6 xl, 463

Various types of sterility are recognized (1) pri mary (2) relative and (3) secondary

Primary sterllity is that type in which the possibility of conception is precluded because of permanent congenital or developmental defects in the structure or function of the renital organs.

Relative sterility is a state in which the absence of conception is attributable to causes which are susceptible of correction. These causes may be structural chemical functional or emotional.

Secondary sterility or what is commonly known as one-child sterility occurs in those women who fail to conceive after the birth of one child.

The successful treatment of sterility in the female depends largely upon the recognition of its causative factors. Any case that seeks relief requires to be studied with infinite care in order to determine the cause or combination of causes which may be opera tive. Cognizance of the many complicated and baffling causes of sterility should cause one to hest tate to undertake its correction with the same non chalance which has characterized most previous efforts in that direction.

The lessons to be learned from a review of this subject would seem to be

- 1 Sterility in the female may be due to many causes some apparent and easily determined others obscure and discovered only after careful investiga-
- 2 Surgical treatment for its correction should not be instituted until an honest and thorough investigation has shown that the sterility may reasonably be attributed to structural changes in the female generative organs
- 3 No investigation can be considered complete which does not in some way include examination of the semen EDWARD L. CORNELL.

Stauffer W H.: The Relation of the Rectum to the Female Pelvic Organs. J Me St M Ass 1916 xill, 228.

The author draws attention to the anatomical relationship existing between the female pelvic organs and the lower bowel

Diseases of the vagina, rectum or urethra and adjacent glands may have a common beginning and the ctlology of the existing trouble be entirely overlooked because of the fallure to make a thorough and complete examination of adjacent organs examples of such mistakes, gonorrhosa and syphilis may exist in one or all of these organs i e., vagina, urethra, or rectum and if not properly diagnosed and treated in each organ failure to relieve the patient will be the ultimate result.

In conclusion, the author urges a closer relation ship between the work of gynecologist, urologist, and proctologist in order to insure the correct diagnosis and therefore the proper treatment in each given case. HARVEY B MATTHEWS.

W A BEDDMAN

Harrar J A. Post Mortem Cassarean Section; a Report of Ten Cases. 4m J Ohn N Y 1916 [axxii], 1046

The author gives a brief review of the literature on this interesting subject and a brief history of ten cases from the New York Lying-in Hospital.

In the series reported three babies were stillborn. It is probable that the death of all these children occurred before the death of the mother. Four babies were born with hearts feebly beating but there was no attempt at respiration during prolonged efforts at resuscitation. One baby gave a lew feeble gaps and died shortly after delivery. One baby alightly asphyriated at birth died on the sixth day of pneumonia. One baby bally asphyriated at birth left the bospital living and well and one cry ing spontaneously at delivery was also discharged living and well.

C H Davis.

Sonnenburg, C. N. 1 Consurent Section Performed with a Pocket Knife After Death of Mother Resulting in Normal and Living Child Indianapol 3 M J. 1916 xiv 240.

The patient had had two uneventful previous pregnancies and no miscarriages. She had marked arteriosclerosis with blood pressure varying during her pregnancy from 180 s to 210 s. The unne contained no albumin or casts. Two days before entering the hospital there was cedema of the lower extremities which continued There was evidence of congestion of both lungs. Endocarditis, myocarditis, and acute dillastion were observed. One morning she had a pulmonary hemorrhage and before the author could reach her she died.

So much time had elapsed in the effort to restore the patient that Sonnenburg feared to wait for the instruments and so performed a cessarean section with a pearl handled knufe, 5,5 inches in length with a 3-5 inch blade. The baby girl was resuscitated in four minutes and has been gaining in weight rapidly. It was a full term infant weighed seven and one-half pounds, and was normal in all respects. Foward L. Commu. Waegeli, C. Interstitial Pregnancy (La gromeme interstitiell) Rev de gynte. et de chi abd 1916 xxlii, 405 441

Internitial pregnancy is rare and Wasgell in a very extensive research of the hierature on the subject has been able to collect only 150 cases, and of these many are very doubtful as both the macroscopic and microscopic descriptions are either lack mag or incomplete. On this account Wasgell rejects 36 cases. Of the remaining 112 cases, namy do not on examination satisfy the elementary postulates concerning which most authors are agreed and such cases if admitted must be taken on faith rather than on the evidence submitted by them.

The interpretation of an interatitial pregnancy is always difficult. It can easily be contouned with an angular pregnancy, with that in a rudimentary uterine cornus, or with a tubal isthmic pregnancy From these considerations and from lack of satisfactory internal evidence Waegeli reduces the number of cases of genuine interstitial pregnancy report ed in the literature to S.

He describes with great detail and exactness the macro- and microscopical features of two cases which came under his observation in the Gynecolog ical Clinic of the University of Geneva. In both cases the macroscopical and microscopical finding demonstrated clearly the development of a left

interstitial pregnancy

In the first case, the uterine fundus was strongly inclined (som of Ruge Simon) the left round ligament laterally inserted and there was asymmetry of the insertion of the adnexe the left being much higher than the right. The feetal cavity is clearly separated from the uterine cavity the hernin of the uterine caducous into the foetal sac showed that this caducous did not continue any part directly with an analogous formation in the ovular cavity Sections from the tube show that there is no sign of an ovular graft. The greater part of its inter stitial portions has no connection whatever with the ovular sac. All the evidence is in favor of a clear intramuscular or intramural insertion of the ovule and not intratubal or intracanicular feetal sac is developed in the muscular tissue itself Neither does the microscopic examination show the least sign whatever of any inflammatory process in elther tube.

In the second case the macroscopic and microscopic findings, which were almost identical in character also establish the development of a left interstutial pregnancy. A muscular septum several millimeters thick separated the uterine and foctal cavities sections of the left tube in the vicinity of the foctal sace show the complete absence of ovular graft. The uterine fundus is quite vertical and the left adness are almost 5 cm. higher than the right. It is quite clear in this case also that the ovule is inserted in the muscular wall surrounding the tube but not in the tubal canal itself and the wall of the fectal sac shows clearly that it is constituted entirely of muscular tissue.

From a further study of the cases Waegeli thinks that the irruptions of the chorfal villodities and their epithelium into the wall of the fectal sac does not occur during the early period of pregnancy and not until it is two or three months advanced.

In the second part of his extensive study Waegelf from a consideration of his own cases and the details furnished by others, endeavors to build up a complete clinical picture of interstitial pregnancy After full consideration of the various classifications of other authors he finally classifies this affection in the following manner

1 Interstitial pregnancy intramural or para mural (a) with evolution against the uterine scron, (b) with evolution against the aterime cavity (c) with evolution in the two above-stated directions: 3 Cansilcular intensitial pregnancy. This classification will, according to Waggell, include every reported case.

Warrell thinks that the euology of interstitial pregnancy! the most obscure chapter in the history of the affection. Having confidered the rious etiological theories submitted be deel nest to expany opinion in favor of one or the other. The truth is probably that different anomalies of the truth is probably that different anomalies of the truth and adorse concur to filliate the interistial insertion of the ovule. Tody we re scarcely more advanced than Velpeau, who in 33 wrote that the mechanism of interstitial pregnancy was still totally unknown.

The vintxoots and ugns of an interstitud need nancy are rarely distinguishable before operation or resol tion. The pregnancy most frequently ends by rupture, this occurring in the majority of recorded cases from the second to the fourth month, although it may extend t the seventh month in rare cases the resolutio if the pregnancy may be by a uterine abortion of the complete vule or by an incomplete uterine abortion. This last occurred i four of the recorded cases. If we'ver the pathological anatomy is char cieratic Macrosconically there is round tumo in the correspond ine pterine corpus. This t mo contain the fortal sac inserted in the parat bal musculature direct consequence of it development is the senara tion of the insertions of the round I rament from the ovarian and tubal [gaments \ muxular wall formed between the uterine must lar sentum was found to exist in 5 of the cases recorded. The absence of such a sept in implies canalicula inter stitial pregnancy with uterin evol tion

But personary the most characteristic sign is the extraordinary position are med by the uterial fundis. This becomes more ed more inclined nill it is almost if not quit vertical. Some thosever disput the pathognomousle at of this sign. In the cases collected by Wegel the sign may present a 3g it was not present in 5 and its presence was not indicated in 15. It was present in both the author's personal cases. While this sign is present in the majority of cases its becare can not be held to be a criterion of disqualification.

not be held to be a criterion of disqualification. Warged discusses the other macroscopic concomitants of intensitial pregnancy the insertio of the round ligament in laterality of the focal sar modification 1 position of the dinear lateral statements of the total sar modification 1 position of the dinear lateral sayments of the total salar modern of the total sayments of the total halt on the graved side in the indicate maj rity of cases being higher than the other.

In the microscopy anatomy the question which dominates all others is that of the formation of caducous in the festal interstitial cavity. Opinions on this are well divided and Waegeli discusses the various arguments without arriving t any very definite conclusions.

The clinical diagnosis, prognosis, and treatment are finally discussed. In the statistics it is shown that in a cases where intervention was made before rupture all recovered. Twenty-nine which were operated upon after rupture gave a mortality of 7 5 per cent The operation of choice is the ex cision of the gr vid uterine cornus and the cor responding tube. Total hysterectomy is indicated ally if there it fection. The rule adopted by the author it immediately operate upon every case of interse tial pregnancy when such a diagnosis is made moreover t is absolutely necessary to interven even in ages where an interstitial pregnancy is only suspected. The dangers of an immediate from a delay who h may at any moment result in a fatality W A. BRETTAN.

File, File Blood Ferment in Pregnancy IIIi el

The author believes the following conclusions express the attitud of most workers toward the Abderhald test.

The Abderhald test is not a media and

The Abderhablen test is not a specific and infallible test for the diagnosis of pregnancy cancer or y other condition

A negative reaction in a given case is of great value as peaking against the possibility of pregnancy 3. A positive reaction must be interpreted as only speaking for the diagnosis of pregnancy and that only in absence of a large number of party-looking cond in its 1 some of which attention has already

been called

4 The ferment are increased in the blood duri g
preguancy. As yet however no way has been
devised f differentiating between these ferments
and the f ments mobilised in many pathologic

cond tions.

The test should be done in all cases in which
the diagnosts of pregnancy is in doubt with a full
knowledge of its limitations and possible errors. It
should be regarded as corroborative evidence
together at the other clinical phenomena.

D JL Born.

Kraus, H. A. Pregnancy Complicated by Syphilia,
10 set M. J. o 6, axx. 5.

If soman has a genital chancre at the time of conception or shortly after it course is often protracted and the ulcerations are deepe and more extensive than usual. Secondary lesions and subjective symptoms are of in aggravated.

Syphills is a frequent cause of abortion and premature delivery especially between the sixth and eighth months. In the majority of cases miscar riagos are caused by the death of the fortus.

The effect of yphilis on the ovum varies. The child may be born healthy and remain so or it may develop signs of syphilis in three to dix weeks, or it may show distinctive signs at birth. Other symptoms may appear which are the result of disease (hermorth ge juundice, etc.) The child may

show various congenital malformations, or it may die before birth, and characteristic lesions may or may not be shown in the placenta following abortion.

Early treatment must be instituted before the middle penod of pregnancy A mixed treatment of mercury and arrente is advised. Children born without lesions and a negative Wassermann should be treated. The author uses a dally injection of some soluble sait of mercury increasing the amount to the point of salivation. A weekly intravenous nejection of o.; grain of neosalvarsan is given with the mercury. D. H. Boyo

Smead L. F: Gunahot Wounds of the Abdomen in Pregnant Women. Tr Am Am Obst & Gynce Indianapolis, 1916. Sept.

The author reports the case of a pregnant woman shot through the abdomen both mother and child recovering. The bullet perforated the colon and the uterus of the mother the placenta, and the child a hand.

Gunshot wounds of the abdomen are more dangerous during pregnancy than at other times. The abdomen should be opened in all cases if possible. The uterus at full term should be empited by cesarean section and at earlier periods if the organ is hadly injured. A uterus during labor is likely to spread any infection which is free in the abdomen and a pregnant uterus is therefore a menace to the patient if perionnitis develops.

The uterus is usually emptied by casarean section or hysterotomy because the abdomen is open.

Hysterectomy is usually not indicated in gunshot wounds of the abdomen unless the uterus is badly lacerated.

Drainage should always be used in these cases and irrigation very rarely

About thirty cases of gunshot wounds of the abdomen in pregnant women are cited.

LABOR AND ITS COMPLICATIONS Freeland, J. R.: Scopolamine-Morphine Anna. thesis in Labor; a Report of Seven Years

Experience. Penn. If J 1916 xix 768

The author uses Merck a scopolamine. He thinks it advisable to confine oneself to one preparation when contradictory results have been obtained by various investigators.

The author's method of administration is the one untilly adopted except that he eliminates much of the mental suggestion that is associated with the mental suggestion that is associated with percel orders, cotton in the patients ears etc. In his opinion, too dark a room interferes with observation of the patient. A dimily lighted but not gloomy room, free from extraneous noises and interruptions, adds to the effectiveness of the drug but carried to the extreme and associated with the other elements of suggestion already mentioned creates an atmosphere potentially harmful to patients in the receptive mental state caused by seconolamine.

Therefore all movements, conversation and manpulations are carried out in a natural manner and not with the hushed mysterious air of mutes at a funeral or assistants at a magician s entertainment.

Great capital has been made out of the popular bellet that a specially equipped hospital is necessary for deriving the greatest benefit from scopolamine. This is of course a nonsensical contention. With a trained nurse capable of counting the fortal heart beat and conversant with the care of patients who have been annexthetized for any purpose, the average home offers the atmosphere of quiet that is claimed to be a necessity. In this one respect, the best-equipped hospital in the world has no advantage over the quiet bedroom to which the patient is accuratemed.

Regarding the effect on the child it has been claimed that a condition of apneas frequently follows the use of scopolamine. The author's results show this to be no more frequent than after any other annesthetic, and it is much more likely to be caused by morphine than by scopolamine. Resuscitation of asphyxiated infants was not required oftener in the scopolamine than in the other cases.

There were no children born alive who died because of failure of resuctation, except one case of cerebral hamorrhage the diagnosis being confirmed by autopsy. The feetal mortality in 410 cases was 8 or a per cent excluding four children that were mucerated. The causes of death in the stillborn infants were cerebral hamorrhage 2 cord around neck 1 cause unknown as no autopsy was allowed 5. Two died after delivery one from stenosis of the larynx and one from cerebral hamorrhage, both diagnoses being confirmed by autopsy.

As to the effect on the duration of labor in 236 printiparse the average duration of labor was twenty two and one-sixth hours. These patients were of all ares.

There is one type of cases in which acopolamine does delay labor and increase the frequency of forceps application that is those patients in whom it produces delinum and uncontrollable restlements.

One point should always be remembered in connection with the question of the duration of labor and that is that a sedative is most needed by patients in whom labor is prolonged and will most often be used in cases of this type to the detriment of the reputation of whatever sedative is used if unqualified statistics are presented. The patients who have short quiet labors require no amesthetic and so lower the average duration of labor in their particular group. On the other hand, scopolamine, if useful at all is useful in cases of inertia and extreme susceptibility to pain.

As regards the occurrence of abnormalities, those in the author a series comprise (orceps 66 or 16 per cent breech 9 or 2 or per cent face 3 post partum hemorrhage 4 or 1 per cent contracted pelvis 7 persistent occipitoposterior position 6 acute chores 1 chronic chores 1 cdampals 6 epilepsy 5 pyrilitis 2 pulmonary tuberculosis 2 lobar pneumonis

exophthalmic golter r heart-disease r, syphills 3 and hydatidiform mole r. None of these can be said to have been caused by the use of scorolamine

Regarding the effect on the consciousness of pain and the effect on the mind of the mother the au thor's result were as follows: (1) complet relief of pain and amnesia 64 or 15.5 per cent., (2) great relief of pain, sleep between, patient waking during height of contraction 336, or 57.5 per cent. (3) marked relief but no sleep 69 or 37 per cent. (4) more free 41 or 10 per cent. (5) delicting reases.

In considering these results and the low percent age of occurrence of amnesia, one point needs cm phasis. The author never deliberately pushes the drug with the object of obtaining annesis, but uses it with the idea that its object is accomplished if the patient sleeps between pains and wakens during them. The harmful effects so often obtained result from conference to set amnesia in all cases.

The utbor suggests that scopolamine be withheld if the patient shows any marked reaction on the stimulative side such as delirium, inconsequential talk, or even the well-known atropine flush which often appears after the first dose in those patients

In whom a second done causes delition.

The conclusions are (1) Scopolamine is a usef I sedative not anserthetic, when not pushed to the extreme of physiologic tolerance. (1) Under these conditions it is without danger to the child. (1) It does not have a retarding influence upon the progress of labor. (4) Suggestion should be avoilled. (5) Injurious mental results can and do commonly occur and care bould be taken to avoid its use in mattents whose make up suggests such possibilities.

Valena, J.A. Pituitrin in Labor II cst 1/1 Ves.

The author draw the following conclusions as to the use of pitultrin in labor

EDWARD L. CORVELL

1. It enables the doctor to use general ansettled to lease the suffering of the patient In many cases where he could not others he give it on account of stopping the properss of the contenence. But this simulates the contractions, hastens the progress of the delivery and at the same tim also is the use of a general anaethetic. This in the a thor's opinion makes piturin one of the greatest.

medicines discovered in later years.

It should not be given without a general amentbetic unless in very small doses, and even

then it is preferable that an anaesthetic be given.

3. The size of the dose should be governed by
the condition of the case.

4 In opposition to may writers, the author believes the struct of the pituitary has a large place in so-called normal labors.

s. He has never seen a y asphysia or any sign of severe compressio of the fortus in connecti n with its use

6 The extract produces strong intermittent contractions the contractions often prolonged above the normal especially when a lirge fose i given Labor seems tiret in tiphys logical har ctir. 7 No sign fitet ni utine ontraction

occurred I any of the tho ses

8 Used In only on c se of miscarring of two

months sta dig to pel th pla nt t had no effect whatever

q. No sign of any rupture f the teru was ofed but the tho belives t might pea fly occur in cases of obstruction that too large lose of the extract.

culation. C IL Davis.

DeLee J B : A Bacteriologic Study of the Causes of Some Stillbirths Preliminary Report J Am M Ass 1916 lzvii 344

Thirteen years ago the author saw a child of a healthy mother born with a temperature of 101, which within a few hours rose to 103 died of streptococcic septicemia, the mother show ine no signs of infection. A year later a physician s wife after a mild pharyngins developed albuminuria and eclampsia. Artificial delivery was performed Out of the child a nostrils pure pus exuded pneumococcus was found in it Several other cases have indicated that the child can become ill in dependently of its mother and may even die the mother being only indirectly affected or not at all

This opens up an immense field for study that we may thus find the cause of many cases of socalled habitual abortion and repeated prema ture labor after viability and before term, and that we may discover new problems of immunity focal infections nephritis during pregnancy eclampsia. puerperal sepsis, blood borne transmissions and new aspects of the transmutations of bacteria

EDWARD L. CORNELL.

Decref: A Case of Obstetrical Paralysis (Un caso de paralism obstetuca) Sielo med 10 6 lai 1 180.

The case is reported of an infant of two months which at birth did not move the right arm family physician stated that the birth had been protracted and that axillar traction was necessitated.

This traction occasioned traumatic lesions of the shoulder resulting in the arm being completely pen dulous and absolutely immobilized

In these cases Decref avails himself of Gaugele's procedure which is to place the shoulder in a position of extension abduction and external rotation form ing a right angle with the arm." This position is maintained by means of a ring which takes the form of a banneret at the end of a pole and which serves also to keep the arm in the position indicated

After 13 days more or less movement begins to he noted since there is a restitution of the articulary elements. Reduction alone as in this case, suffices generally for complete restitution. If the immobility has occasioned trophic or degenerative lesions electrotherapy is indicated. W. A. BRESTAN.

Thomas, T T: Obstetrical or Brachial Birth 1# J Obst N 1 1916 Ixxiii, 577 Patey

The author reports 11 cases of brachial birth pals) and gives an interesting review of the litera

ture together with his views regarding the etiology and treatment of this condition. He rejects the plexus theory for most cases.

His interest in obstetrical palmes resulted from observations on adult brachial paisies from injuries to the shoulder region. He claims that a palsy due to injury to the shoulder region and associated with an ankylosis of the shoulder joint which disappears with the restoration of normal motion to the shoulder joint must be due to an injury to that joint He believes that this conception also applies to obstetrical palsies, and that the treat ment based upon it is the best

The author bases his treatment upon the simple principle of restoring as nearly as possible the normal function of the shoulder joint From an experience with 24 palsied arms in 23 patients he found that when there was no displacement in the shoulder joint a perfect recovery could be obtained from exercise alone. In all of his cases of birth palsy with the typical internal rotation of the limb and the characteristic limitation of abduction and external rotation as old as two or three years he has not yet failed to find present a posterior subluxation of the

shoulder loint

The strongest evidence of a traumatic origin at birth of these subluxations is the bending downward and forward of the anterior portion of the acromion which is practically always present An injury to the brachial plexus cannot explain it. It is obviously due to the same pressure which pushed the humeral head backward during delivery will not show the bent portion of the acromion as the patients are too young. However he has found it by operation every time except on a patient in whom the acromion showed distinct evidence of pressure. The absence of the normal humeral prominence under the posterior edge of the acromion and the bending downward and forward of the anterior portion of the acromion will establish the diagnosis of a postenor subluxation. It is important to recognize it at or soon after birth and its diagnosis is so difficult then for the reasons al ready given, that he does not hesitate to mildly etherize the young patient in order to assure the diagnosus. In doubtful cases he takes advantage of the anasthetic to make sure the humeral head is in good position and fix it there for six weeks by a light

cast with the arm in abduction and external rotation Operative reduction of these dislocations is in its infancy and as yet no method of operation has received much attention. C. II DATES.

GENITO-URINARY SURGERY

ADRENAL, KIDNEY AND URETER

Payne R. L., J : Unitateral Harmaturia Associated with Fibrosis and a Multipl Microscopi Calculi of th Renal Papillas. Surg Grant & Ohr., o 6 xxiil. 76.

Reference is made to previous experimental work by the author in which acutely developing vascular lesions were eliminated as cause of symptomicss unilateral renal harmorrhage

The author then reports a case of symptomless unilateral hamaturia i which bisection f the kid nev showed microscopically a pormal cost parenchyma but every papille presented a cherry red appearance typical of angloma.

The kidney was removed and careful microscoru atudies disclosed an absence of pathological find ings in the cortex or parenchyma proper but the papille showed definit chroni inflammatory

changes.

These changes consisted of () an overgrowth of connective tissue (2) multiple microscora calcula. (a) dilated capillaries with the small alcul in close apposition or the capillaries surrounded by the on nective-tierue proliferation (4) a network of dilated capillaries on the surface of the papillar may f which were ruptured with free blood escening

These numerous though small varices were evi dently the source of the hamorrhag and the in ference is that the numerous calculi, aided by the connective tissue they had originated, succeeded in causing an obstruction t the venous return with anhaequent dilatation of the capillaries and re sulting varicocities.

The paper is illustrated with microph tographs showing the microscopic calculi, the connective tissu proliferation, and numerous dilated cardi laries which have ruptured on the surface of the

papille with free blood escaping. The author claims that this is the first case re

corded in which there is definitely shown the cause and source of a symptomiess unifateral harnaturia The facts presented would lend further weight to the contention of those who believe chronic inflammation to be the cause of unliateral enal

hemorrhage.

Bressit, Dr. Surtical Replacement of th. Prolapsed Kidney Surg Gyare. & Obst 19 6 xxilli oo

The approach to the kidney advocated is by exact dissection of the tissues in the lumbar region oc casioning the least trauma, or injury to the tissues encountered, at the same time facilitating deep manipulation in delivering the kidney

The skin noision is fou inches - beginning at point immediately boye the angle formed by the lost rib and the erect spung and extending to a pol t mmediately bove Petit triangle terminal fibers of the Litisamus dors! e now incised along the line of their atta hment to the erector spanse and the m scle is transferred to the center margin I the would 1 not ion is next mad In the upper area or superior triangle of the lumbar I see moreductely bell wind parallel with the twelfth db, this cision being stended inward and outward as far may be found necessary Lated roul erve usually found t th inner side The kidney is then directly apof this i citi proached by blunt di section through the fatty

The finger is hooked int the cellular the u bout one of the poles preferably the upper and the orga delivered. The lity psul is completeby freed from it to hment to the kidney and a crementic locus in of the fibrous capsul is made on the posterior urf xtending almost from pole t pol and t with on of the billum. Two sustains g sutures of leget ble dyed silkworm gut are passed completely round the noles penetrating the attached portio of the fibrous capsule at several port to fix their position. When the replaced these sut res are passed through musel fascia, and skin and tied ver bolster of todof rm gauze

prop or shield, formed by the crescentic portion of the fibrous c psule separated from the posterior risc of the Lidney is sut red to the under surface of the lumbar fascia t prevent the fatty cars le which is not removed but forced anteriorly from wedging between the raw posterior surf ce of th kidney and the heath f the quadratus lum barum. The fascial incision I closed with a continuous sut re of plain cateur No The latisamus dorsa is sutured to it original position with plaications N s The skin should always be united with a perms ent suture as the edges of the upper portion will separate by pressure from the bolster of gause if the uture material is soluble The allk worm gut sutures are tied on the inner aid of the loops on the nineteenth day after operation and the patient is all wed to get out of bed immediately The sutures are removed any tim within the next two days.

Abell, I Ghant Ureteral Calcul : Anomalous Development of th Genito-Urimary Tract Surg Gyest & Obst o 6, axill, 33

The case reported was that of a male white ared 52 whose personal history was perative for acute severe illness and venereal infection. The patient applied for relief of pain in his back of ten days duration. Irregular left lumbar pain was first noted at 18 at 28 similar pain was noted on the right side. Latterly pain recurred monthly never sufficiently severe to require oplates and until the present attack persisting only a day or two. Here tolore relief had been afforded by rest hot baths hot water bottle etc. Between paroxysms there was urinary frequency four to five times daily during an attack once to twice daily. Blood was noted in the urine on a number of occasions.

The patient was thin but well-developed and muscular pulse 100 temperature 100 z h heart and lungs normal 11ght kidney palpable tender apparently as large as a medium-stued grape fruit The left kidney not palpable no tenderness on that side. The urine was a muddy color acid a g 100 marked trace of albumin occasional blood

and pus cells calcium oxalate crystals amorphous phosphates moderate number of bacteria

Cystoscopy showed that the bladder was practically normal the left urtered ordine appeared normal the catheter rendily entered the renal pel vis. The ordice of the right ureter was cedematous the catheter encountered obstruction at 25 cm. The urine from the left kildney showed no albumin nor pus an occasional blood-cell blood count normal

Radiography of the calculous pelvic portion of each ureter showed the left to be of moderate size the right extended from the sacro-iliac joint to the mentus. The diagnosis was bilateral ureteral

calculi right-aided hydronephrosis.

The operation consisted of a bilateral griditon incision enlarged downward by incising the rectus sheath the peritoneum was displaced menially the ureters were approached extraperitoneally. There was considerable thickening about the right ureter and it was separated with difficulty from the surrounding structures. The ureter was incised at the pelvic brim and the calculus removed by traction After a similar procedure on the left side the ureternal incisions were closed by interrupted categut. The external wounds were drained by strips of rubber sheeting.

The post-operative history was unevenful the patient resuming work at the end of the third week. The right calculus was oblong with a distinct curve at either extr-mity length 7,5 cm circumference 7 cm weight 24 grams the left stone was more ovoid

weight a grams

The Herature shows that Desgula removed ureteral calculus irregularly triangular 26 by 23 nm weighing 10 grams Baker 94 grants Parker over 36 ounce Bovée, 236 by 144 by 14 inches over 36 ounce Bovée, 236 by 144 by 14 inches over 36 ounce Bovée, 236 by 144 by 14 inches over 36 inches long 6 mm. to 1 cm. in diameter (2) 236 inches long by 136 inches wide Specklin 11 cm long weight 51 grams Federoff length 10 cm width of a bean farael (1) length 13 cm circumference 9 cm. weight 544 grams (2) length 17 cm cir cumference 9 cm. 10 gram weight 17 cm circumference 9 cm. 10 gram weight 145 grams

Lloyd length 55 inches circumference 25 inches Morris nearly 6 inches long Cibbon 32 inch in

diameter nearly round

The second case occurred in a female white aged nineteen who had been married three years with no pregnancy nor menstruation attack was diagnosed as appendicitis. When the second attack occurred the patient was taken to the hospital Her pulse was 120 temperature alsdomen markedly distented exqui ite tenderness in the lower zone. While her figure was typically feminine examination revealed the absence of a vagina the external genitals were normal in appearance. The unne was acid trace of al bumin slight sediment few blood-cells many ous cells and rod-shaped bacilli. The blood count showed hamoglobin go per cent white cells to 500 polynuclears 82 per cent. The tender mass in the left pelvis was thought to be retained and infected menstrual secretion

Cerliotomy with median incision disclosed a pelvic kidney in front and to the left of the knero-like syn chondrosis. The right kidney uterus tubes, and ovaries were alvent. The appendix was removed The operative finding was pyclitis in a single pelvic

Lidne

Three weeks later urine from the ureter and the bladder was negative upon culture. Andlographs showed the renal pelvis to be normal in size and shape with a single ureter three of four lacks long. A cystogram showed the bladder pressing upon the kidney the latter producing a variation in the night and vesical outline. The rectum was in the right

In the literature Anders cites one case of single kidney based upon 92 600 automies the occurrence of the anomaly was one in 1817. He refers to 285 cases in the literature. Among 36 gross renal and ureteral anomalies in the Mayo clinic during five years 12 were horseshoe and 6 single type Thomas reports a case of pulvic kidney in a female diagnosed prior to operation for pelvic disease, the vagina and uterus absent Cullen mentions a case of a girl of seventeen with right pelvic kidney vagina uterus and left kidney absent tubes and ovaries prolapsed in the ingulanl region Bissell success fully reimplanted a right pelvic kidney. A single kidney has been observed at autopay by Ward Glazebrook Secher, Stengel and others 1 olk removed a single right kidney located in the pelvis the patient perishing after thirteen days of complete anuria Mayer and Nelkin speak of subparietal traumatic rupture of a solitary right kidney

BLADDER, URETHRA AND PENIS

Granger A: The Use of Oxygen in Cystography, with a Preliminary Report on the Use of Oxygen in Pyclography Am J Reculpus and Ill and the Use of Cystography Am J Reculpus Conference of

1916 lil 351

Beginning in 1900 the author began using washed and filtered air to distend the urinary had been an effort to obtain better cystograph—but found it was abscess with extensive destruction of tissues, long standing cases of hard fibrous scientic veskles, cases in which the veskle and ampulls are product g symptoms referable to the ureter and selected cases of extreme nervous origin unaltered by the usual treatment.

Veskulotomy is considered in all cases of sperms torrhora all cases of pas and blood in the ejeculate and following massage and in the acut extarrhal and uppurative types. If G Hawas

Crowell, A. J. Urinsary Retention Due to Prostatic Obstruction. Unit & Calen Rev. 9 6, xz. 55.

In the first type of protatale obstruction, provided sacress, the author believes that the protest should be detailed periteetily without opening the urethra. In the second class of cases, prostate hypertrophy the author believes i perineal prostatectomy for the reason that the wound and the hidneys ir both drained from the most dependent point the perineum. He believes that the mortality following the perineal operation is n t as great as that following a large companied by an absence of the prostate the absence cavity also can be better drained through the perineum.

In malignant disease of the protate a tentloo is called to the f or that the prost te, its capsule the seminal vesicles, and the bladder trigone can all be removed perineally. In perf rining this operation the growth may be entirely removed the only draw back being that incontinence of uri usually ensues. He recounts two cases in which he has used the Young punch to remove a protatiot bar. In one case a man of 53 who had bad kidney function, 4 ounces of residual urine and was in poor physical condition, the punch operation was entirely successful. In the next case, a man 35 years of age who had 16 ounces of residual urine, the median har was removed by the punch. After the operation he was able to empty his bladd r without difficulty.

B.S. Basano a.

Gordon, G 5.1 The Internal Sphincter Following, Prostatectomy Surg Green & Obst 19 6 xm,

After removal of adenomata through the internal pilinter the sphilotet on regalating its full functional power often forms a raised crescentic fold which in ratio to its take obstructs urbandon, with the result that there still remains some bnormal back pressure at urbandon on the bladder unters, and kidneys which encourages the condunance of infection and interferes with renal accretion. Beblad this obstruction is a pouch of residual urine in which stome may form. If the free edge of the sphin ter has been denuded and its purse tring action is strong enough it may bit terate the outlet enterly of or text healing may occur. The uthor believes the bitruction hould be dait with at operation and he greats the entire removal of this flap or that it be list and pilled to the denuded prostate bed.

SURGERY OF THE EYE AND EAR

EYE

Wilmer W H: Three Years Experience in Scierocorneal Trephining in Glaucoma. Arch Ophile 1916 xlv 333

Case histories of patients on whom sclerocorneal trephining for glaucoma was done are presented the author stating that by reason of the small number he has been able to carefully follow up the cases.

His results have been very favorable tension being lowered and pain relieved in nine eyes after the La Grange operation or iridectomy had failed and miotics had been used in many cases over

periods of years.

He protests against the present unfavorable attitude toward the operation he believes that the pendulum is awinging too far to the opposite from the procedure's enthusiastic reception, and states that in his opinion sclerocorneal trephining is the easiest safest and most effective method yet sug gested for permanently reducing excessive tension.

Late infections he believes, can be lessened by taking care to dissect up all the subconjunctival tissue with the conjunctive in order to make the

flaps as thick and protective as possible.

Synechiæ lenticular opacities, hæmorrhages and relapses are said to be no more frequently met with after this than after other methods of operating and it has the advantages that both eyes can be operated upon at the same time the patient does not have to be long confined it does not reduce the visual fields or cause astigmatism to an accountable extent there is only a negligible risk of the loss of vitreous and no danger of the escape of the lens and the operation may be repeated. S S HOWE.

EAR

Moure E. I: A New Method of Examining the Vestibular Labyrinth (Sur un nouveau mode d'examen d'labyrinthe véstibulaire) Bull de Acad de med Par 1916 lxxv 413

For some years past Moure has made it a practice in examining the vestibular labyrinth to submit the patient to a series of experiments in which provoked nystagmus occupies an important place. Accord ing to the duration and intensity of the nystagmus and the time it takes to appear he deduces that the labyrinth is normally hyper or hypo-excitable

The number of labyrinthine affections occurring during the war has afforded many opportunities for putting this method into use. W. A. BRENNAN

Hays, H : The Corroborative Diagnosis of Mastoid itis by Means of the X Ray A F H J 1016 dl 1163

The author cites cases to show the value of the roentgenogram in corroborating the clinical evidences of masteid disease. He does not insist upon the necessity of having an \ ray taken before a diagnosis of mastoiditis can be made but he does consider it of more value than a consultation particularly in atypical cases or when weighing the evidence for and against operative interference. Besides this knowledge a roentgenogram shows the position of the sinus the size and shape of the mastoid and the extent of zygomatic cells. Otto M. Rott

Lent, E. J : Chronic Suppurative Mastolditis Accompanied by Intracrunial Pressure. J. Indi na Si M. Ass. 1016 ix, 200

A case is cited in which operation disclosed the presence of a large cyst apparently not dependent upon the middle ear infection, as the fluid in the cyst was sterile The patient ultimately recovered after symptoms of meningeal irritation had super vened. The cyst was drained and later allowed to become infected after which the discharge was gradually lessened in amount and finally ceased.

The author briefly discusses the question of cerebral cysts dividing them into four classes (1) parasitic, (2) traumatic, (3) apoplectic (4) and degenerated neoplesms.

1 Parasitic cysts are due either to the cysticerous or echinococci.

2 Traumatic cysts are not very clearly defined in origin They may be explained on the ground of long-continued circulatory disturbances with consequent local accumulations of serum, or shrink ing of cerebral tissues in the region of injury the result of sclerotic changes in the cerebral substances the contraction leading to the formation of a vacuum which becomes filled with fluid derived from the surrounding membranes

3 In apoplectic cysts the blood-clot contracts and changes from a red to a brownish color due to the transformation of the hemoglobin into herea The pigment is diffused in the neighboring tissues giving a yellowish tinge the detritus is transformed and absorbed so that a cavity remains containing fluid, the so-called apoplectic cyst

4 In degenerated neoplasms cyats may be f und on microscopic examination to be the end result of an almost complete degeneration of a glioma

ELLEX J PATTERSON

Mayer E. Angloma of the Larynx. Med Rec

From a study of his own case and the forty others found in the literature the author reaches the follow ing conclusions

ing conclusions

1 Angioma of the larynx is a rare disease of curring mostly in adults and the proportion of males to females is approximately four to one

2 It may be mistaken for cancer

- 3 Endolaryngeal removal of a portion of the growth for diagnosis, or its complete removal in this manner is fraught with danger and may have serious results.
- 4. Laryngofissure, removal and suturing the nucosa, are entirely safe and feasible procedures.

 Orro M Rotr

MOUTH

Mayes, W. C. and Wilson W. and C. F. Focal Infections Results of Overcoming Same South M. J. 1916 ix 490

Many diseases, the etiology of which has been obscure are due to metastasis or absorption of toorias from a primary focal infection and in order to conserve the best body economy it is essential not only to treat symptoms but to remove the primary focus or at least overcome the infection.

In diseases due to focal infection if a cure is not effected by the removal of a diseased focus or if further metastases occur then further search must be made for another focus by exhausting every aid the laboratory \ ray and one a diagnostic ability

afford

If for anatomical reasons the focus cannot be removed or the infection in same controlled, often the removal of a diseased tonail or the draining of an apical dental abscess or accessory nasal sinuses will allow the body economy so to recuperate that a cure will be effected in the original oftending focus Filial Patterson.

Horsley J S : Cancer of the Mouth and Tongue with Special Reference to Metastases in the Neck South M J 1916 it 512

In account is given of eight cases of carcinoma of the mouth and tongue illustrated by post-operative an 1 micrographical results of the pathological sections. The author lays stress on the harmfulness of the procedure of exclaing a specimen of the growth and allowing some time to clapse before operation is done. In case pathological examination is necessary for the diagnosis he advises that the excision of the specimen be done with the cautery and the complete operation follow immediately.

In the three cases which are alive and living from one to four years after operation there was no primary incision for diagnosis made. The five who are dead all had incisions made into the tumor mass

to confirm the diagnosis.

The results of operations for carcinomata of the floor of the mouth are discouraging unless a wide dissection is made including in the block a part of the jaw bone. The author has found that the slow cautery is the best method of dealing with massive recurrences.

HARM C SLOAN

Hofmann, E.: Melanosarcoma of the Buccal Mucosa (Melansarkom der Mundschleimhaut) Muchen med Wehnschr 1916 bill 322

The case reported by Holmann was in a man of 58 who in January, 1911 presented himself with a tumor which had first appeared about a year prevous. This was situated in the external part of the ascending branch of the maxillary about the size of a cherry hard, dark-colored and with linear radisting furrows. The tumor with the proximate tissue was extirpated under local anaxithesis by the galvanocautery. In the following week the dark lines which traversed the velum were cauterized and an energetic salvarsan treatment instituted. Two months after the first operation a dark discolored spot showed in one of the extremes of the cicatrix which had resulted after the operation.

The tissue in which this spot was situated was circumscribed by the thermocauter; and removed radiotherapy treatment being instituted later. Histologic examination showed that this tissue as well as the original tumor which was removed was

typical melanosarcoma.

The patient was lost sight of until 1015. For about a year the patient lost weight rapidly fosing 4.5 kilos in weight in little more than a month Blackish streaks were ejected in the expectoration and microscopic examination of these showed melanic nuclei identical with the primary tumor

In the lobule of the left lung there were catarrhal manifestations which suggested the existence of metastases. The patient was again put under salvarsan treatment. W. A. Barwax
